ping, but it is generally understood that three Corn crops shall not follow in succession. The Wheat crop is on an average, about 18 bushels per acre; the Red Straw Lammas is the kind chiefly sown. It is almost universally drilled in. The Wheat crop is followed by Oats, or in some few instances by Barley. The average Oat crop varies from four to five quarters, that of the Barley crop is in general less, than thirty bushels. The Oat stubble is pared and burnt in autumn, and after two ploughings the land is sown to Turnips or Swedes in May or June. This is still generally done broad-cast, but the practice of bouting and drilling is gradually becoming more general. The Turnip crop is not, on an average, above 12 tons to the acre. This low average is, perhaps, partly owing to the circumstance that no horse hoes or drill-harrows are used to stir the land during the growth of the crop, and also, to the practice of not skimming them out sufficiently. This is the only crop in the course where dung is applied to the land. The Turnip crop, with the exception of a small portion of it, which is carted home for the labouring oxen, or for any fatting oxen that the farmer may have, is eaten on the land by the sheep. This prepares it for the Barley crop, which is sown after a single furrow in the months of April or May. Clover seeds, with the common Rye Grass, are sown with the Barley. They in general remain two years on the land: an average crop of about 15 cwt. of Hay is cut. After lying down two years, the land is ploughed up for Wheat, which is sown about the beginning of September, either on a single furrow or after a double ploughing. The first furrow in the latter case is called *rafturing*, that is, the land is half ploughed, each furrow-slice being laid on its breadth of flat land. This is dragged and harrowed, and a second furrow is then taken. The plough in common use is the Beverstone wheel-plough, having a wooden mould-board. It is drawn either by three horses or four oxen. Besides these crops, one-sixth part of the farm is, in general, in Sainfoin each year. This is almost useful plant to the hill farmer. The soil of the Bath-stone is well suited for it; and large crops are grown where Clover would fail. It is sown and kept down for six or seven years—or long, in fact, as it will remain in the land. When the land is once tired of it, it is long before it will grow it again, and thirty or forty years are generally made to intervene before a second crop is taken. Immense crops of it are frequently cut during the first two or three years; 40 and 50 cwt. per acre have been cut under these circumstances. It is always broken up for Turnips or Swedes, and, being pared and burnt, a thick coat of ashes is laid over the land. In some parts of this district, a system of burning is followed, which is termed stiffe-burning, by which, according to the testimony of those who adopt it, the crop of Turnips is greatly increased, without any additional expense of cultivation. This way of performing the operation, as it was told me, has at length falsified the old proverb, that "Burning, though good for the father, is bad for the son." It consists in laying sods around the heap of Couch, Stubble, &c., to such an extent, that the combustion is retarded though not stopt altogether. The vegetable matter is thus preserved, and, instead of being sent to the winds in smoke, is chiefly returned to the soil. This seems to be the reason of its superiority to the old plan. With regard to the labour of the farm, about one-half of the ploughing is performed by ox-teams, four in each, and one-half by horses, three in each team. The oxen are in general bred on the farm, put to work when three years old, and either sold as working oxen or sent to the butcher, after an attempt to fatten them, when five years old. Four teams, it is calculated, will plough three acres a day; and certainly, considering the shallowness of the furrow, this is a light day's work. With the exception of ploughing and general farm work, all other labour is generally done by the piece. Thus, hoeing the Wheat in spring is let at 4s. an acre; hoeing the Turnip crop three times at perhaps 30s., and paring Oat-stubble, at 8s. an acre. Men and boys only are employed, except at harvest-time. Women are seldom seen in the fields at work with the hoe in their hands, although it might be more economically done if they were employed. This is certainly the best-cultivated of any of the formations occurring within the district; and although the resources of the soil have certainly not yet been driven to their utmost stretch, they have been driven harder than those of the soil of any other district we shall have to mention. There is also a much greater degree of interest taken by the farmers in this district in the progress of agriculture generally than there is anywhere else on the district. There has been a great step taken here in the improvement of agricultural practice within the last century. This district was, not 100 years ago, one uninclosed common, let to farmers at 1s. an acre, who sublet it to others. It was broken up once in five or six years, and a crop of Oats taken, seldom exceeding double the quantity of the seed sown. The land lay inactive during the intervals between these crops, and it was overrun by a few sheep, which in some degree kept down the Couch which there flourished. The generation which saw the Turnip introduced has hardly yet gone by. The farmers who were condemned for attempting its growth, out of the garden have hardly disappeared. Since then the land has been inclosed, and the Turnip and the Swede have taken that place which they must ever do in a good system of farming.—*H. S.*

DRAINAGE OF SURFACE-WATER FROM HEAVY LAND.

The very various and conflicting opinions as to what is perfect drainage, convince me that practice without theory is like a ship without a compass—dangerous, and uncertain, and expensive. Having cut, during the past year, with good effect, many miles of drain, I will describe its action, and state what I consider to be the true theories of perfect drainage.

My operation being different to the usual custom, I beg to submit my theories and practice for discussion, approval, or disproof. The question of drainage is far too important to remain longer in obscurity. The Royal Agricultural Society will do an essential public service by deciding the point.

Theory.—That in perfect drainage, twelve inches deep should percolate and leave the land, in less than twelve hours from the time the drains begin to act, the difference in time being equivalent to the proportion of water the earth chooses to retain for its use by capillary attraction.

That to effect this, the subterranean area of porosity, *i. e.* the surface of the drains, should nearly equal the surface to be drained, so that if the space to be drained were one square yard, the sides and top of the drain should present an area for percolation equal to nine superficial feet, minus the allowance for pressure.

That the continuance of water in the soil longer than it would remain by capillary retention, is injurious.

That the earth and roots will abstract from the passing water those gases for which they have an affinity, and in which they may be deficient.

That the form of drain should be deep and narrow, as affording the greatest area of porosity at the smallest cost, increasing the quantity of porous earth, available to roots.

That the material for filling the drains should comprise the greatest durability with the least power of capillary attraction.

That where pipes are used, their material should be durable but porous; their form not round or square, but a very narrow and deep oblong, the object being to get a large area of porosity.

That small, round, hard pebble-stones, with a pipe over them, as used on my farm, seem to present all the advantages desired, viz., the impossibility of choking by superincumbent earth, resistance of pressure from the sides, absence of capillary attraction; the round hard stones having but little mechanical affinity for the water, and offering but small resistance to its passage.

That the passage of water in a pipe or drain is always quicker than its percolation through the earth or material of the pipe.

That no drain should much exceed 100 yards in length (fifty or sixty would be better), without opening into a leading drain of greater dimensions. If the drain were in any part full, it would delay percolation.

That neither Bushes, Straw, or other perishable material, should ever be used in a drain.

That the deeper the drainage, the better the crops; but in no case should any portion of the drain be nearer to the surface than 18 inches.

There should be a leader to every 300 yards of drains, giving it ample capacity.

That there should be an open ditch, without fence, for every seven or eight acres drained. The absence of an occasional open ditch is what renders so much drainage useless. Long continuous narrow streets, without frequent outlets, get frequently obstructed; the same may be said of drains—a full drain with a slow egress sadly retards the filtration of water. Drains should be never more than half full of water the other half air. In this way the superior weight of water causes proper filtration by displacement of air and replacement of water by quick passage.

That the rapidity of percolation depends on the subterranean area of porosity and the depth of drain combined. Shallow drains want a greater area of porosity than deeper ones; because (as water presses equally on all sides towards the vacant space in the drain) the deeper the drain the greater the weight and column of water. Consequently, the greater the pressure the more rapid the filtration: filtration at two feet will be double that at one—at four feet four times as great, and so on in proportion to the superincumbent weight of water pressing equally on all sides towards the drain. It is on this principle that deep pipe drains act quicker and lay dry a greater extent of ground than shallow ones—consequently, the deeper your drainage, the smaller may be your area of subterranean porosity. Pipes at the depth of five feet would hardly need stones, the pressure being about two-and-a-half pounds on every square inch at first; and as the water escapes and diminishes, so will the drains run slower and slower, in a ratio proportioned to the diminished pressure.

Now, although my drainage is considered the most perfect in the county of Essex, I only consider it one-fifth as perfect as it should be. My drains have one foot of subterranean porosity for every five feet of surface, instead of having five feet: still as it is expensive even so, I must be content with it; and I will assume it to be the minimum of perfect drainage.

During the recent nineteen hours' rain, after a very dry time, the stones and pipes poured out an immense volume of water, which, on the second, third, and fourth day, gradually decreased; proving my calculations correct, for if my drains had been perfect, it would have all run away in seventeen hours, instead of eighty.

In comparing notes with a farming friend of mine, who has bush drains from 200 to 300 yards long, in the same quality land, he said, "I know not what has become of the water, for none has appeared in the ditches;" and he seemed quite surprised at my drains running so much. What is the inference?—that bush and straw drains of great length are perfectly worthless as compared with pipes and stone drains of moderate length.

In fact, on one field I drained about three acres the same time, distance, depth, and soil, with reeds or bands of straw tightly fitted over the vacant space, and find it as compared with the tile and stone drained part, almost useless, so much so, that we shall re-drain it.

The cause of my fields easing the water is, that its stagnates and remains in the soil, keeping the roots cold, wet, and sour, resulting in late crops and densely working land. I hope after this, we shall hear no more of scud or bush draining. From the moment our land was ploughed after draining, no water has ever run off the surface, whether in winter or spring, although our fields have a pleasant slope. So far my draining has answered, although I still maintain it is only perfect in degree. It would have been real economy to have spent another 5*l.* per acre, and carried out my theory completely. I am not able to say which answers best, a pipe only, the full size of the drain, or a pipe and stones. The latter I give the preference to, the stones having less capillary attraction. I consider drainage almost as important in a very dry season as in a very wet one. This spring we had a practical illustration of it at Tiptree. The crops never looked yellow as they used to do, but always a healthy green, and the very first rain caused so amazing quick growth. It is very easy to perceive that porous drained land on a cool bottom keeps moist in dry weather, by capillary attraction (like lamp sugar testing on moisture). At night the dews fill its surface. No such effects can take place in sodden land, with gaping cracks, and a baked impervious surface.

If I am wrong in my theories or practice, I shall feel obliged to any gentleman who will correct me, my object being to arrive as near perfection as possible. Permanent Grass on very stiff clays must be ploughed up before the drains can act. The impervious pan requires to be broken up. This may be a subject of regret, but it ought not to be; for I quite agree with Mr. Morton, that no permanent Grass can keep so much stock per acre as the Turnip culture and green crops, fed, folded, or stall fed, nor is it so profitable. Grass land is therefore a national loss, employing less labour, capital, and affording less profit than it would do if cultivated with roots, green crops, and corn.

Drainage of Springs.—This must always be effected by drain-pipes (without stones) fitting into each other so as to form one continuous unbroken channel; half-circular pipes, fitting on each other, are sometimes used; if properly loaded they answer, but are not so secure as the whole pipes.

I think we may lay down as a safe theory:—That as the pressure of water is from below, and frequently as much as fourteen pounds on every square inch, that spring drainage should be deep, so that the superincumbent earth be equal to resisting the pressure on the pipes. That the pipes should be always large enough to contain air as well as water. That no stones, bushes, or straw should be used in spring drains, it being evident the immense pressure I have mentioned would quickly choke them with earth.—*I. J. Mechi, 4, Leadenhall-street.*

Home Correspondence.

Drainage: Debenham Farmers' Club.—For the information of your Mid-Lothian contributor, Debenham is a small market town in Suffolk; and there are many farmers in its neighbourhood (and men of education too), who are Goths enough to doubt the efficiency of tile drains, "as done once to last for ever," and still prefer those filled with straw, stubble, or plashings, for clay land. They do not think the tiles will wash away or wear out, but on tenacious soils they often find such a portion of clay worked into the drain as to prevent the water running, where by chance or otherwise they have been induced to try tiles. The drains made in the Suffolk fashion last from 16 to 20 years; and if Mr. Girdwood will take the trouble to look into the Royal Agricultural Society of England's Journal, at Mr. Pusey's Report on Draining, he will find much of the matter of discussion at the Debenham Farmers' Club Meeting recorded in an article by the Rev. C. Hill. Tile-draining having been only tried a very few years, the Suffolk farmers would give as a reason for adhering to their old system, that it has been in use in their county nearly a century, and found very beneficial, long before tiles were even thought of, and they are loth to give up entirely an old friend, who does not lead them into expense more than they are sure of having repaid, and taking up a new comparatively untried and more expensive one. Still if it can be proved that Suffolk farmers can reap any gain from the use of tiles, they will be immediately used for all or nearly all drains even in the Debenham district; and many persons, I am told, are actually using them now, where their landlords are sufficiently liberal to supply them. Of the utility of draining land in an oblique direction, I can state an instance which I witnessed last autumn. Whilst looking over a farm not far from Debenham, where part of a field was drained down every other furrow (of ridges each three yards wide), from top to bottom of the field, and the other part obliquely across the ridges at six yards apart—the field being rather hilly but not steep—I made inquiry why that part drained longitudinally had one wet furrow and one dry one, whilst the other part drained obliquely was all equally dry, as much so as any part of that drained down the furrow. The only answer I could get, and the conclusion I arrived at was, that it being drained obliquely across the field, the surface water ran down each furrow, and fell into the drains as it came to them; and that on the part drawn longitudinally every other furrow had no drain under it to receive the water. As I do not pretend to know how the strata lay, or even

the principle of how water gets into the drains (except that it will run down hill). I am hardened in my predisposition for trashyness drains, by practical observation, contrary to the written theories of the day. I have also seen the same result on my own farm in a field drained part each way. On many of the strong clay lands in Suffolk, unless drains are made not further than six or seven yards apart, the water will not draw into them; therefore Suffolk draining becomes more expensive than your Mid-Lothian friend contemplates in his calculation. I believe the Suffolk system is not a complete and absurd one, as long leases are not the custom with the small landowners there, and farms frequently change their tenants; and though I am sure in this case to be called an old-fashioned close-headed Suffolk farmer, defending his customs against modern improvements, I can only plead guilty to a fear of casting away the old broom before I have proved the new one, even though it be recommended by the march-of-intellect-men of the present day; for I have found by experience that their advice is very apt to march the profits off a farm to a very quick time.—*A Farmer and Valuer, Newmarket.*

Mr. Johnson's Register of Implements.—With reference to your notice of Mr. Johnson's book of advertisements of agricultural implements, I fear that your readers may be mistaken in expecting it to be a complete Register of Implements shown at the Royal Agricultural Society's Meetings at Southampton. The fact of the matter stands thus:—Mr. Johnson's book contains only the names of 18 makers of implements, while the catalogue of the Society contains 97 names of makers of machines and implements, and is a larger book by 58 pages. I hope in justice to the makers whose implements are not noticed in Mr. Johnson's book, you will give insertion to this.—*A Subscriber.*

Allotment System.—Where this system is carried out with a view to give assistance to the hard-working artisan and labourer, presenting to them an opportunity of employing their spare time, with a prospect of obtaining a profitable return for their industry, the scheme offers great advantages to society at large. The visible change in the habits of the population of a district where the plan is liberally and fairly practised speaks sufficiently in its favour. It is, however, to be feared that it is too often considered a speculation by the landholder, and a means of acquiring a higher rent than is given by the farmer for the same description of land, thus rather burthening the poor man than benefiting him. In many instances another abuse also creeps in, which savours of the Irish middle-man. An individual takes a piece of land at 3*l.* per acre, and lets it out again at 6*l.*, which being far above its value, the poor man cannot pay his rent, and his crops are seized; thus, in many neighbourhoods bringing into disrepute a plan which, in itself, is calculated to do so much good and elevate the character of the lower orders. Cultivation by spade husbandry being superior to the use of the plough, if any difference is made in the rent, justice demands it in favour of the small tenant. Accommodation land close to a town, occupied as a market garden, is, of course, of increased value, in its relative position, compared with that at a greater distance, apportioned to labourers, and to which they have to walk one or two miles, either after a hard day's work, or before they commence their accustomed employment. The quantity of land allowed to the head of a family should never exceed a quarter of an acre, and generally speaking the sixth or eighth is enough. Where the object is merely to assist in housekeeping, and not as a main source of income, mischief arises from granting it with more land than he and his family can till during their leisure hours, and yet not sufficient to maintain them without other assistance. This dependence upon the land interferes with their common vocations, and reduces them to greater distress than they would have experienced without the allotment. Half measures are always bad. By a judicious distribution of lots according to the strength of a family, better cropping and manuring will be insured, rents better paid, and the honest man will not be screwed out of his last farthing to meet the exorbitant demands of his landlord and *protector*. An argument has been used in favour of high rents, viz., "A man need not take the land unless he likes," and the best answer to this is, "A drowning man will catch at a straw." Where the labour market is over-stocked, any nominal rent may be asked and promised, but the day of reckoning is a proof of how far either party have acted wisely.—*Falcon.*

Rooks.—[We have received the following communications on this subject since the date of No. 28, and we give them in an abridged form.]—In winter, while the weather is fresh, rooks follow the ploughs, which are then almost constantly in motion, to obtain the larvæ and worms turned up by them. In frost and snow they resort to roads and dunghills, and frequently attack stackyards, tearing the thatch from the heads of the stacks, and devouring the exposed grain. They are sometimes, also, known to eat Swedish Turnips, and do some mischief in that way, as the broken bulbs generally fall victims to the frost. The principal damage, however, of which they are guilty in winter is their attacks upon the young Wheat. In spring they certainly do eat grain of various kinds, scattered by the hand of the sower, but not to any great extent. Their principal employment is following the ploughs for insects, &c., and I have no doubt much good is done by them in this way at that season. Nevertheless, the first-sown fields in a district generally require watching by the farmer. In the beginning of summer, when the Potatoes begin to sprout, rooks do a great deal of damage by digging up the sets, and thus completely destroying the plants. The fields must be well looked after at this period by the farmer, and the birds scared away until the plants are of a larger size. It is often necessary to watch Potato fields for three weeks and sometimes even for a longer time. In summer, too, especially if the weather be hot and dry, rooks often do some damage to the ripening stacks in the stack-yard, tearing off the thatch, and carrying off whole heads of grain into some neighbouring field to be devoured at more leisure. Pasture lands, however, are the great resort of these birds in summer, and there they do much good, destroying numbers of grubs and other insects. They often also render a service to the farmer, by spreading abroad, in their search for insects, the droppings of pastured animals, particularly horses, as these, when left alone, produce rank tufts of coarse herbage. Towards the end of summer rooks may sometimes be observed in Turnip-fields, pulling up the young plants; but this, I am of opinion, is merely to get at some lurking insect. In autumn the farmer is again a sufferer from the depredations of the rook. Whenever the corn begins to ripen, it is attacked by flocks of rooks, and much damage is often done, especially in spots where the crops are at all laid. When the grain is cut and stacked, too, they do a good deal of mischief. When the Potato crop is nearly ready for taking up, rooks often attack it, digging into the sides of the drills and extracting whole tubers, and sometimes the farmer is again, as in spring, compelled to have his fields watched. When not engaged in these spoliations, rooks are generally to be found in pastures; or if any ploughs are at work, searching the upturned furrow-slices. In early autumn, too, they very frequently resort to moors and uncultivated ground, most probably in quest of insect food. As far as my experience goes, I am disposed to think that rooks should be encouraged to a certain extent, but that they should not be allowed to become too numerous in any district. Their numbers ought, I think, to be kept under, lest the supply exceed the demand for them, and the rook turn thief at all times and not now and then merely.—*A. J., Roxburghshire.*—On turning to Bewick, which I have interleaved, I find the following note:—"In the winter of 1829-30 I saw a Barley-stack unroofed, and heard of a cottage in the neighbourhood which had shared a like fate in the course of a few hours. The rooks, driven to this food by the severity of the weather, performed their work of destruction as effectually, though not so deliberately, as the bunting is said to do, by the author of the Journal of a Naturalist.—*Herts.*" This summer I have seen them taking to a new food. A farmer neighbour had put down several loads of ground bones, but on account of the drought did not spread them. The rooks have been very busy round these loads, and have carried off and dropped in a field belonging to another farmer really a considerable portion of this valuable manure. [They probably attacked the grubs merely, which will breed in a heap of half-rotten bones.] Having thus said what I can against this bird, let me now become his advocate. He only does this mischief when in distress. I do not believe, except under necessity, that he is graminivorous, though I have known him pick up acorns. In confinement he will leave corn for grubs of any kind. Neither, setting aside his destruction of insects, &c., is he altogether an unprofitable bird. As food, two years ago, I saw no less certainly than 200 young rooks given to the poor, and other persons had their share. I would certainly say to the farmer, the rook is your friend, despite some faults;—and who is perfect!—*Cantabrensis Jr.*—In the *Gazette* of June 15th there is an article headed *Rooks*, by "Acer." Its author is evidently a great crow-fancier, or he, surely, would never have taken the radicle of the Oats, preparing to root, for the wireworm, gorged with the milky substance of the Oat." Any person may satisfy himself of the fact, that all grain, after being cast into the ground a certain time, shows "a white streak, extended lengthwise." I cannot see any cruelty in killing these black robbers, so convinced am I of the injury they do to the crops. I have no reason for doubting that the evil they do to the farmer so far overbalances any good they may do, that it would stand in the ratio of 99 to 1, from one year's end to the other. I am not so fortunate as to be "owner of a considerable rookery;" yet, being in possession of a patch of ground in the shape of a small farm, I have had frequent opportunities of quarrelling with these birds—being placed about midway between two considerable camps of the enemy, which harass me on every side. In spring, when sowing commences, the damage they do is great; next come the Potatoes, which suffer in their turn after the grain crops have got beyond them; next the Turnips in their season suffer (this being the scarcest time of food for them in the whole year, winter excepted), so that they are forced to turn up manure in the drills in search, doubtless, of wire-worms, &c., and thus they root out the Turnip plants, and ruin the crop; next comes the early-ripened grain, the first thing in the shape of plenty that they have had for some time—they luxuriate in the midst of this all harvest time; but when the fields are well nigh cleared of grain then commences their second period of famine, and they are ready to pour down in myriads on the patches of Wheat that are here and there sown through the country, (this is not properly a Wheat-growing country). Lately the birds have begun to make havoc on Turnip fields during winter, principally among the yellow and Swedish kinds, by picking holes in the bulbs, and thereby admitting water, air, and *frost* to them. Last winter I did not leave a single Turnip field but what suffered less or more, and it was no uncommon thing to see whole fields where not a single Turnip of any considerable size had escaped them. I am convinced that there is no farmer in the neighbourhood but what suffers from 10 to 20 per cent. of loss upon his crops by the depredations of these birds: in my own case, for the last 12 months I am quite sure that I would not have suffered half so much, though I had had all the wire-worms in the county of Forfar to contend against, instead of the herculean rooks, as "Acer" would have them to be.—*Peel, Loch Lintlithan, Angus.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Monthly Council was held at the Society's House in Hanover-square, on Wednesday, the 7th of August; present, T. Raymond Barker, Esq., in the chair; Col. Austen; De Bunsen, Esq., M.P.; F. Burke, Esq.; J. Kinder, Esq.; J. Parkes, Esq.; J. A. Ransome, Esq.; and Prof. Sewell.

The Earl of Egmont, of Enmore Castle, near Ashmore, Somersetshire; and John Cheetham, Esq., of Norton House, near Yeovil, Somersetshire, were elected Governors, and the following gentlemen Members of the Society:—

Henderson, Colonel, Mayor of Southampton
Curtis, William, Netheravon House, Amesbury, Wilts.
Davis, Robert, East Woodhay, Newbury, Berks.
Gurney, Charles, Launceston, Cornwall
Hobby, D. Peter, Colquite, Bodmin, Cornwall
Drew, John Watkins, Southampton
Young, George Edgar, Broad Chalk, Wilton, Wilts.
Sinford, George, Bishopstone, Wilton, Wilts.
Newton, Thomas F., Bogdean, Salisbury
Cousins, Robert, Norton Farm, Sutton-Scotney, Hants.
Gilbert, Major, Bartley Lodge, Southampton
Bainshaw, Rev. Charles Simon, Trinity Church, Southampton
Taylor, John Oddin, Hardingham, Norwich
Powell, Colonel W. E., Nanteos, Aberystwith, S. W.
Harvey, Thomas, Kegilbeck, Falmouth, Cornwall
Johnston, Charles, Claremont, Cheshunt, Herts.
Bolcan, Sir J. P., Bart., Ketteringham, Wymondham, Norfolk
Treemer, James, Rauceford Lodge, Lyndhurst, Hants.
Long, John, Marwell Hall, Twyford, Winchester
Bowser, William James, Merton, Surrey
Edwards, Thomas, Compton House, Stockbridge, Hants.
Lyeight, Admiral Arthur, Southsea, Portsmouth
Glover, Rev. Frederick, R. A., Rector of Charlton, Dover
Bury, Edward, Hanslope Park, Newp rt-Pagnel, Bucks.
Dorchester, Lord, Greywell, Odiham, Hants.
Talbot, C. R. Mansel, M.P., Margam Park, Neath, S.W.
Kemp, James, C., Liverpool
Smallpiece, Job, Compton, Guildford, Surrey
Smallpiece, William Haydon, Guildford, Surrey
Haydon, Joseph, Guildford, Surrey
Campbell, Major T. E. (7th, or Queen's Own Hussars), Kenilworth, Warwickshire
Martin, R. P. Brounker, Compton House, Salisbury
of Germans, Earl of, Port Eliot, Devonport
Campbell, John H., Exton, Bishop's Waltham, Hants.
Bowring, John, Wick, Worcester
Drummond, Henry, Albury Park, Guildford, Surrey
Cosens, Thomas, 10, Chandos-street, Cavendish-square
De Grey, Hon. Brownlow N. Osborn, Fawley, Southampton
De Grey, Hon. and Rev. Frederick, Copdock Rectory, Ipswich
De Grey, Hon. George, Fawley, Southampton
Damer, Joseph Angel, New Farm, Winfrith, Dorchester, Dorset
Owen, William, Blessington, Ireland
Russell, E. R., Southampton
Speke, William, Jordans, Ilminster, Somerset
Tinker, William, Crook House, Devizes, Wilts.
Hocken, Rev. William, Great Endelion, Camelford, Cornwall
Jolliffe, Sir William G. H., Bart., M.P., Heath House, Petersfield
Clarke, Charles, Aldborough House, Lincoln
Sanders, S., Perchill, Newport, Isle of Wight
Coles, Colonel, Wells, Somerset
Burrell, Walter, 5, Richmond-terrace, Whitehall
Hooper, George, Jun., Combe Bank, Kent
Huskington, Sir Henry, Bart., 34, Montague-square, London
Pepgate, Simon Fraser, Fitzhall, Midhurst, Sussex
Fryer, John, Hints, Tamworth, Staffordshire.

FINANCES.—The *Chairman of the Finance Committee* laid before the Council the Monthly Report of the state of the funds of the Society to the end of the past month; from which it appeared that the current cash balance in the hands of Messrs. Drummond at that time (including a residue of 300*l.* on account of the subscription of 1000*l.* received from the town of Southampton) amounted to 2848*l.*; and the capital invested in the public funds to 7700*l.*: the Council, before leaving Southampton, having defrayed the expenses of the London police, amounting to 125*l.*, and placed at the disposal of the stewards and director of the yard, out of the deposit of 3308*l.*, in the hands of Messrs. Maddison and Pearce, the Society's Local Bankers, the sum of 1000*l.*, to meet the immediate claims of a miscellaneous character connected with that department. The Council then proceeded to vote the discharge of the following claims, as recommended by the Finance Committee:—

	£
Contract for the Yards and Pavilion at Southampton (balance of account)	1751
Do. Council Dinner	405
Do. Pavilion	560
Prizes awarded at Southampton	1315
Mileage, &c., to the Judges of the Show	354
Miscellaneous Bills connected with the Southampton Meeting	60
Books for the Library	154
Binding and Carriage of Journal	100
Miscellaneous Bills on general account	286
Total	£5051

TRIAL OF IMPLEMENTS.—Communications in reference to the trial of implements at Southampton, were received from Mr. Burke, Mr. Smart, Mr. Clayton, and Mr. Coates, and were referred to the Stewards of that department. The Secretary was directed to communicate with the Judges of Implements, and request them to furnish the Council with a statement of the implements submitted to trial; of the results of such experiments as were made; and, generally, with an expression of their motives for their respective awards; together with a notice of such implements as may, in their opinion, deserve special commendation or encouragement.

VETERINARY SCIENCE.—1. *New Epidemic.*—Prof. Sewell reported to the Council upon a letter referred to

him at a former meeting, received from Mr. James Dixon, of White Moss-farm, Cheshire. In that communication Mr. Dixon stated that until he had adopted the treatment of bleeding his cows immediately on their being attacked with the prevailing disease (termed the "New Epidemic"), he lost several; but none had died since he had put that measure into operation. He urges at the same time, in the most strenuous manner, that particular care and caution are required to keep a continual watch over the animals, and apply the remedy at the very instant that the symptoms of the disorder make their appearance; he, on this promptness depends all the value of the measure. As soon as the symptoms are perceived, he recommends bleeding without delay. —Professor Sewell informed the Council that this was the practice he had been in the habit of recommending; and he believed that the losses which had been sustained by the owners of animals from this complaint, had arisen more from want of close attention to their condition, and to the first changes in them from health to disease, than from any other cause; and he accordingly took that opportunity of earnestly recommending Mr. Dixon's watchful care over his stock to all other farmers in general. The first principal step of bleeding having been taken in due time, Professor Sewell would recommend the administration of the usual laxative medicines, and the application of external stimulants, to be left to the judgment of the nearest practitioner.

2. *Diseases of Domestic Animals.*—Professor Sewell then reported that the examination at the Royal Veterinary College being concluded for the session, ninety-three pupils had received diplomas; several of whom had also obtained certificates as having attended the lectures and practice on cattle, sheep, and other domestic animals; in which branch of their profession he thought their services to the farmer would be better secured by Agricultural Associations and Farmers' Clubs in the country engaging them, at fixed moderate salaries, to settle in localities where they are most likely to be required. This plan had been adopted with great success on the Continent, but it was there effected as a Government measure, and had become a long established law.

3. *Rabid Animals.*—Professor Sewell informed the Council, that keeping in view the object of the Society's connexion with the Veterinary College, he had decided on devoting the period of his professional recess during the present autumn to a practical inquiry into the most successful means by which the virus of rabid animals may be counteracted, and the fearful results of hydrophobia obviated. He accordingly requested the co-operation of the members in carrying out this inquiry, and would himself willingly pay every expense connected with the sending up to the college, from any part of the country, of such sheep, lambs, or calves, as may unfortunately have been bitten by rabid dogs during the late hot weather, or should become liable to a similar infliction at any future time. He mentioned small ruminating animals only, as being more easily managed when labouring under the worst or most violent symptoms of the disease, than horses, cows, or bullocks, which under such circumstances are not only almost unmanageable, but highly dangerous; and when such were intended to be sent to him, he would feel favoured by a previous notice by letter. The animals thus requested might be conveyed in the ordinary railway trucks or cars, or sent by canal boats. By the latter mode, Professor Sewell had received a heifer from Worcester a few years ago: sheep and lambs have been sent in covered carts; but the most rapid conveyance is preferable. A sheep or two might be put into crates used for earthenware, and the expense of engaging an entire car, be thus obviated; while the animals would be less annoying to the railway agents. Should the disease commence on the journey, the animals should be tied by the legs, and be well littered with straw. Net muzzles might be worn, or sent along with the animals in order to be in readiness. Professor Sewell felt, however, never had any fear of rabies being communicated by the bite of any animals but those of a carnivorous kind, including swine as such. Of all the numerous cases of canine madness he had seen in horses and other animals, he had not observed a single instance in which they were unable or unwilling to drink water freely. He had always found the disease commence (with a single exception) from the third to the sixth week after the bite had been inflicted. If, therefore, it should not manifest itself in the stock sent to him by that time, he would return the animals to their respective owners free of expense. In conclusion, the Professor submitted to the inspection of the Council a series of highly interesting coloured drawings, exhibiting the morbid results on the brain, nerves, and other anatomical structures of the animals which had died from the ravages of hydrophobia; and he trusted that his request might not be considered an irregular one, as he was anxious to effect an immediate communication with the members, and to lose as little time as possible in obtaining objects for his intended research.

English Silk.—Mrs. Whitby, of Newlands, near Lymington, Hampshire, presented to the Society, at a previous meeting of the Council, a specimen of the silk grown and wound off at her residence, made with only a dozen of the cocoons just formed; and accompanied the Council with the following interesting narrative of her operations:—

"I have during several years past cultivated the Mulberry (mostly used in climates where silk is grown of the best quality) and fed silkworms upon it with great success. I have had an opinion on the quality of the silk produced from them, which encourages me to hope my example will be followed by others, as a means of profit to the agriculturist, and affording employment to the industrious classes.

"I was led to the undertaking by hearing, in 1835, as I was travelling in the north of Italy, of an English gentleman, 'who had doubled his capital in three years, and who received 10 per cent. on that laid out on a silk establishment near Milan;' and wonder was expressed that the culture had not been tried in England. Agricultural produce had been at a high rate in England, and it was difficult to find profitable employment for the labourer. I determined to try and introduce the cultivation of silk. I saw the young Mulberry-trees in Lombardy blown aside by the force of the N.E. winds at each spring gales are here by S.W. gales. At this period, if [illegible] duration had prevailed, and the ground round Milan was covered with snow, and from hoar-frost. I knew that around Florence the nights were cold, and the weather uncertain, even as late in the spring as the 1st June. Judging from all this that the climate of England was equally favourable to the growth of the Mulberry, I ordered from a nursery garden at Turin 100 standard trees and 1000 dwarf Mulberry-plants of the sort called —'Of the Philippine Islands' (*Morus multicaulis*). This sort produces much larger leaves than the Italian wild White Mulberry, or that which in England is cultivated for its fruit. Its growth is rapid, and it is easily propagated by cuttings, which strike as readily as the Willow.

"My plants did not arrive in England until April, 1836. I treated them according to the directions given in Mons. Burden's book, and I did not lose one. I even gathered leaves from them the same year. I bought half an ounce of silk-worms' eggs at Novi, which is said to produce the best silk in Italy, and thus laid the foundation of a small establishment, which, I hope, will be the means of spreading the culture of raw silk throughout England, and in the course of years render her independent of foreign resources. I have had no difficulty whatever in rearing the silk-worm. I possess an old loft over an unused stable; in the former I have reared the worm; in the latter I placed a silk reel. Although my cocoons were pronounced "good," and would bear a comparison with the specimens I brought from Italy—although they were exempt from the diseases which I understand carry off at times whole colonies there —although I imported a silk reel from Italy, and went to a great expense in having a scientific apparatus laid down to heat the water, I found insurmountable obstacles in winding off the silk *fit for the loom*. I tried year after year, in vain: it was bright and beautiful to look at: it was pronounced by Mr. Bonorardis, of the firm of Prevost and Co., 24 A, Cateaton-street, to be of "*good quality, and sufficient bone and brightness*, but the winding was without the 3 necessary for the loom." This opinion encouraged me to send to France for a person acquainted with the process; the result you have in the specimens I have sent you. The yellow silk is the growth of this year, the white that of cocoons kept during my many years of trial. I have several pounds already wound off, equally good, and the French girl, aged 19, and another (English) of 15, are now busy at work winding more. All the expense I have incurred in the apparatus above named, is so much money thrown away; the wheel I have imported this year with this young girl from France, is cheap, simple, and effectual; it is also so easy of accomplishment that three of my household can wind with facility, besides a cottager's wife who is employed at six pence a-day to attend upon the worms. The eggs can always be retarded so as not to be hatched before the Mulberry is ready to put forth sufficient food. In France and Italy the hatching begins about the 1st of May; I find a month later preferable. All the books I have read describe a temperature of 75° to be essential. I have proved by eight years' experience that the insects thrive better at one much lower. In damp or cold weather, I have a very small Arnot's stove lighted, which regulates the temperature to from 65° to 70°. Ventilation is more necessary than extreme heat. The expense of this stove is trifling—as indeed is every thing connected with the cultivation of silk. This has been a dry season, and the leaves in consequence fewer and smaller than usual, but the same difficulty has occurred in France, and the father of my little winder writes word, that he was obliged to throw away this year 40,000 worms for lack of food. Mine would have suffered also had not my friends in the neighbourhood assisted in supplying me with leaves of the Red Mulberry. A scarcity of leaves happening occasionally is no proof that it cannot succeed; look around at our fields. Where are the spring crops of Barley and Oats? Where are the Turnips which ought now to make them green? Checks from bad seasons will occasionally happen to every produce of the earth in all countries; but in general the Mulberry of the Philippine Islands grows luxuriantly and multiplies freely in this part of England. The expense of an establishment such as mine would be small: that which I have incurred in my unassisted efforts to succeed must not be considered as necessary by any one willing to take advantage by my experience; and I am as desirous to see the culture of silk become general, that it will give me much pleasure to answer any inquiries you may wish to make, or give any information in my power. I almost fear I shall have tired you with this recital; but I knew not how to make it shorter, if to be clear and convincing. Be it remembered there was the same prejudice to France as now exists in England against this branch of agriculture: it was attempted to be overcome by Henry IV.; but, what is tried to enforce by edict, became general as it became better known. All I desire is, to make it known, that others may try in other parts of England.—P.S. The worms of this year were reared partly from eggs saved by myself last year, and partly from insects I purchased from Signor Anegoni, 16, Church-st., Soho."

The best thanks of the Council were returned to Mrs. Whitby for the favour of this communication.

Southampton Meeting.—At a Special Council held at Southampton, Nov. 18th, on the part of himself and Mr. Shelley, as Stewards of the Implement Department, reported the unanimous satisfaction of the Implement-makers with their arrangements, when it was moved by Col. Austen, and seconded by the Marquis of Downshire, That the best thanks of the Council be presented to Mr. Mills and the Steward, for their exertions as Stewards of the Implement Department; and for the trouble they had taken on behalf of the Society in the Implement show-yard, as well as on the trial ground. This motion was carried unanimously.—On the representation of the Earl of Ducie, on behalf of the Implement-makers, it was resolved,—That the exhibitors of implements be permitted to read the foregone proof of Mr. Parkin's Report (prepared for publication in the Journal) in the Society's Rooms, but not to make extracts from it, or publish any part of it.

On the motion of the Hon. Capt. Spencer, it was resolved,—That no examined or spayed animals be allowed to be exhibited at the Country Shows of the Society.

It was decided,—That in future the business of the Society be adjourned on the Saturday of the previous week, at 4 o'clock in the afternoon, from the office in Hanover-square to the place of the Annual Country Meeting.

Resolutions were passed expressive of the high opinion entertained by the Council of the conduct of the police at the Southampton Meeting.

Shrewsbury Meeting.—The following General Shrewsbury Committee has been appointed by the Council:—Earl Spencer, *Chairman*; Hon. R. H. Clive, M.P., *Vice-Chairman*; Duke of Richmond, Lord Portman, Hon. Capt. Spencer, Col. Austen, T. Bensley, Esq., M.P.; Thos. Raymond Barker, Esq.; Col. Challoner; J. W. Childs, Esq., M.P.; Sir Andrew Corbet, Bt.; John Cotes, Esq.; Jas. Deeble, Esq.; C. Emery, Esq.; H. Gibbs, Esq.; H. Gibbs, Esq.; W. Ormsby Gore, Esq., M.P.; W. G. Hester, Esq., M.P.; W. Fisher Hobbs, Esq.; Sir John T. B. Johnstone, Bt., M.P.; W. Miles, Esq., M.P.; Philip Pusey, Esq., M.P.; R. A. Slaney, Esq.; W. Shaw, Esq.; J. Villiers Shelley, Esq.; H. S. Thompson, Esq.

The following Special Show-yard Committee has also been appointed:—*Chairman*, H. Gibbs, Esq.; *Stewards*, Earl Spencer, Hon. Capt. Spencer, S. Druce, Esq.; W. Miles, Esq., M.P.; J. Villiers Shelley, Esq. Mr. Manning, of 251 High Holborn, has been engaged as contractor of the works for the Show-yard and Pavilion.

Notices of Motion for the Monthly Council in December.

Mr. Fisher Hobbs to move:—

I. That the Journal Committee be requested to prepare—
1. A printed List of the Members of the Society, with their addresses, for the general use of the Members.
2. A Catalogue of all Implements, Models, &c., that have been presented to the Society.
3. The Charter and Bye-Laws.

II. That the Judges shall be appointed by the Council from a list of nominations made by the Members of the Society at large at a General Meeting, and on the report of a Committee to whom such list shall have been referred.

Hon. Capt. Spencer to move:—

I. That Governors and Members of the Council shall have admission, under certain regulations, to inspect the Cattle on the Wednesday after the Judges have delivered in their awards.

II. That the Council take into their consideration the details connected with the appointment of the Judges.

Mr. Barclay, M.P., to move:—

That at the future Country Meetings of the Society, the Cattle-Show shall be open to Governors and Members of the Council at 9 o'clock on the Wednesday afternoon.

Communications.—The following communications have been received, with the thanks of the Council:—

1 The Right Hon. Sir George Rose, M.—Results in the employment of the Halmahult Bovella.
2 Capt. Watkins (Bramley-st.)—On Sea-sand as a Fertiliser.
3 Mr. Meehi—Communications on Agricultural Improvement.
4 Mr. Towers—Results of Dibbling Wheat.
5 Mr. Grant—On Fences.
6 Mr. Sheppard—Results in the Use of Guano.
7 Lord Bridport, Mr. Spencer, M.P., and Mr. Curtis—Observations on Insects attacking Green Crops.
8 Mr. Saul—On a Wheat-grub.
9 Mr. Grove—On Kentish Barley.
10 Mr. Hayter, M.P., Mr. Blaker, and Mr. Shackburn—On Apparatus for Steaming Food for Cattle.
11 Mr. Bean—On Parochial Allotments and Drainage.
12 Mr. Carson—On Guano.
13 Mr. Bowers—On the Vernon Harcourt Wheat Hoe.
14 Col. Austen—Communication from M. D'Arbuy (Member of the French Chamber, Dept.)—On the subject of his attendance at the Southampton Meeting, and thanks for attention shown to himself and the Baron Malet.
15 Dr. Ure—Present (on the part of Mr. Knight, of Foster-lane) of cake of this Linseed.
16 Kingsford and Thompson—Present of one of their Double Receiving Hatchets.
17 Mr. R. Smith—Present of Tiller Rope.
18 Mr. Quilter—Extract of Translations of the New York Minutes, and further supply of Indian Corn.
19 Mr. Cuthbert—On Publications against Incendiarism.
20 Mr. Milner—Suggestions for the re-publication, in a cheap form, for the use of Members, of Works on Agriculture, in imitation of the Surtees, Camden, and Sydenham Societies.
21 Duke of Richmond—Request of a Report on Border Agriculture.
22 Mr. Fisher Hobbs—Communication from Dr. Baker, on the Inoculation of Sheep.
23 Mr. Bolton—Treatise on the Growth of Wheat, Gypsum, &c.
24 Mr. Eaton—The Western Agriculturist (Axminster) No. I.
25 Mr. Blair—The Farmers' Magazine.
26 Dr. Bellamy—Lectures on the Education of Farmers.
27 Messing, Burnand, and Co.—On Guano Agency.
28 M. Chaumel—On Asparagus in Poland.
29 Lassell and Co.—On Conveyance of Stock by Steamers.
30 Mr. Osborne—Papers connected with the South East Herts Agricultural Society.

31 Mr. Morton—Meteorological Observations in reference to the Prize offered by the Society for the best account of Pragmatics of Weather.
32 Mr. Pearce—Present of Back-band and Tug for Gig-horses.
33 Mr. Burgess—Communication on Glanders, &c.
34 Messrs. Morton—On Bray's Draught-machine.
35 Mr. Menta—Paper on the Economy of Manures.
36 Sir Edmund Filmer, Bt.—On the Encumbered Estates of the Society.
37 Mr. Sparks—On the Rot-water.
38 Earl of Essex—On [illegible] Employment of Steam on a Steam.

Together with Reports of the Royal Veterinary College, Chippenham Agricultural Association, Royal Cornwall Society of London, Transactions of the Highland and Agricultural Society of Scotland, Caledonian Agricultural Society, and Farmers' Club.

Announcement.—The Chairman declared the Council to stand adjourned to Wednesday, the 4th of September; and failing a meeting on that day for want of a requisite number of members, further adjourned to Wednesday, the 6th of November, for the despatch of business. The Council then adjourned accordingly.

HIGHLAND AND AGRICULTURAL SOCIETY.

The annual West Cattle show of this Society was held last week in Stirling. On Wednesday a meeting of the general committee was held, for the purpose of completing the preliminary arrangements for the meeting. The chair was taken by the Earl of Kinnoull. Mr. Campbell having read the report of the local committee, Sir C. Gordon, the secretary, laid upon the table the Society's new medal, and read an abstract of the entries of stocks, which he stated were larger than upon any previous occasion. The number of lots was 1403; amongst which were 222 Ayrshire cattle, 98 West Highland cattle, 160 horses, 117 sheep, 134 lots of butter, 83 lots of cheese, and 176 implements. The meeting was the largest number ever entered before was 1974, in Edinburgh, in 1842. A dinner took place in the evening at the Trades-hall, and was attended by upwards of 200 noblemen and gentlemen; the Earl of Kinnoull in the chair. Thursday was the day appointed for the show of the stock, dairy produce, implements, &c., and for the allocation of the prizes. As a proof of the immense extent of the present Exhibition, it may be mentioned that the names of the exhibitors occupy no fewer than 27 closely-printed octavo pages, containing stock, implements, and seeds. Of the Short-horned breed there were no fewer than 29 bulls entered for competition, many of them most splendid specimens. Of the Short-horned breed there were 15 cows offered for competition; and of these, one belonging to the Duke of Buccleuch, and another shown by Sir T. J. Tradescant Trafford, of Trafford Park, Lancaster, and bred by Mr. John Fowler, attracted much notice.—In the Ayrshire breed 21 bulls of various ages were shown, the great majority of which were from this and the adjacent western counties. In this class 99 cows were shown, many of them perfect pictures of the breed. There were also some beautiful heifers and calves among the Ayrshires.—Of the West Highland breed there were 16 bulls exhibited from the counties of Perth, Argyle, Banff, and Dumbarton. The show of Horses gave great satisfaction.—In the class of Stallions above, and according eight years old, there were 38 competitors. From the counties of Lanark, Renfrew, Stirling, and Ayr (from the former especially) there were some beautiful animals.—Of entire Colts there were no fewer than 19 shown, and of draught and breed Mares there were 45 competitors, from the counties of Lanark, Renfrew, Dumbarton, Edinburgh, Haddington, Stirling, Ayr, Dumfries, &c.—In the class "Pairs of horses of any age, adapted for agricultural purposes," there were eight competitors, all of them very fine animals.—Of Sheep the entries were very numerous, and under this class a pair of South American Alpacas, accompanied by a young one, two months old, were shown by Mr. A. Cartwright Stirling, of Craybarnet, which were purchased from the stock of the Earl of Derby, in July, 1843.—The Implements exhibited were also numerous beyond all former precedent, and contained many modifications of implements in present use, which may prove highly valuable. The following are the awards in this department:—For the best collection of Agricultural Implements and Machines, ten sovereigns, to Mr. Robert Law, Shettleston, Glasgow, for the best collection; five sovereigns, to Mr. James Wilkie, Uddingstone, for the best workmanship, &c.—For a new and useful Agricultural Implement or Machine that has been satisfactorily tested in actual work, not previously exhibited in competition, seven sovereigns, to Mr. Andrew M'Kerrow, Hillhouse, for his Antler Plough; and three sovereigns, to Mr. John Watt, Lundie, for Plough with Apparatus for lifting Potatoes.—For a useful improvement in the construction of Subsoil Ploughs, five sovereigns, to Mr. James Wilkie, Uddingstone, for Subsoil Plough with Improved Mould.—For a useful improvement in the construction of the common two-horse Plough, whether for the object of the lifting and turning over the greatest quantity of the soil in a given time, with the least resistance to the draught, and which performs the work in the same time a fair and efficient furrow for ordinary or for seed, seven sovereigns, to Messrs. Robert Law and Sons, Uddingstone; and three sovereigns to Mr. James Wilkie.—For a useful improvement in the construction of Barn Fanners, five sovereigns, to Mr. William Cleghorn, Musselburgh.—For a useful improvement in Reaping Machine, seven sovereigns, to Mr. David Crais, Stevenarton.—For the most useful improvement in the construction of any of the Implements used in the cultivation of the Turnip and Potato crops, five sovereigns, to said Mr. James Wilkie; two sovereigns to Mr. Alexander Reid, Stewarton; and two sovereigns to Mr. John M'Gill, Sandrum.—For the most useful improvement in any of the Utensils or Machines used in Dairy Husbandry, five sovereigns, to Mr. Robinson, Lisburn, Ireland; and two sovereigns to Mr. Richmond, Salford.—For the most successful introduction of any Machine or Implement that is generally approved of in the practice of Agriculture in England or elsewhere, or a modification of the same, and which has hitherto been but little known or employed in Scotland, five sovereigns, to Mr. William Crichkill, Beverley; and a silver medal to Mr. Houston, Johnstone Castle.—For a Weighing Machine, adapted to general farm purposes, capable of weighing stock or produce, dead or alive, from the weight of a sheep to that of a loaded cart, and which will indicate the addition of one-thousandth part of the mass to be weighed, five sovereigns, to Mr. Thomas M'Culrick, Garalian.—For an improved method, whether patented or not, of manufacturing Drain Tiles or Pipes, whereby the price will be reduced; the Tiles or Pipes to possess the requisite qualities of usefulness and durability, and satisfactory evidence as to the price to be produced, ten sovereigns, to Mr. Etheridge, Southampton.—Besides the above, the Judges awarded various premiums in money and medals for articles not within the range of those specified. On the evening of this day the great dinner of the Society took place in the City Hall; about 1200 gentlemen sat down, presided over by the Duke of Richmond.

FARMERS' CLUBS.

North Cornwall.—At a late monthly meeting of this Club, a large party visited a field on which Mr. J. S. James had tried the effect of covering Grass with layers of Straw. The Straw had been spread over about one-third of the breadth of the field, and through the entire length from east to west. Mr. James caused the Straw to be raked off for some width up and down the line of division, and from several patches in different parts. The difference was very marked: where no Straw had been laid, all the Grasses were thin and short, and the field appeared almost as brown as the soil itself. But where the Straw had been spread, the Grass presented a lively green, and in quantity was thick and matted, corroborating Mr. James's statement of the enormous increase. He had cut and weighed it, and the increase was at the rate of a ton to the acre. The Chairman had brought from Woodley six turfs, in order to show the meeting the effects produced by Strawing the land. He also answered some objections which had been made. The increased growth evidently did not arise from contact, for the high Grass, on which the Straw principally rested, was scarcely at all acted upon. It was also clear that no unfavourable effect was produced in changing the quality of the Grasses; for they retained all their original properties—there was no new Grass, but all were very much improved. That it was not to be attributed to atmospheric influence, or a diminished evaporation from the soil, was proved from the fact that the rush had been equally susceptible of the effect. There was but one question to be solved, and that was the question of agency; the increase in quantity and quality had been proved to demonstration.—A paper was then read by Mr. Shephard, On the System of Cropping in the District—its Defects and Disadvantages, with Practical Hints for its Improvement.—He said, when I proposed to lay before you some remarks on the subject we are met here to discuss, I did not sufficiently reflect that if it were properly treated, it would include a review of nearly all our agriculture. It is a subject of great interest to all, including as it does the means of providing employment for our labourers, and the means of supporting from our own soil a rapidly increasing population. The first course of cropping I shall mention is that adopted in this immediate neighbourhood, viz.:—Potatoes—Wheat—Barley—Clover, the Clover cut for Hay and secondly for seed, the whole of it upon one dressing being planted with Potatoes. This system, confined however to this more immediate neighbourhood, has been in practice ever since my recollection, and still continues. And, notwithstanding the occupiers of the land find its production annually diminishing, they still persevere in the same objectionable course. Possibly, however, this may arise from its affording to the artisans, and the other working men of the town and vicinity, great facilities for getting a few yards of Potatoes annually. I will admit this to be of considerable importance to such parties, and would be the last man to urge anything that would deprive them of the advantage: the system may, nevertheless, be improved without doing this, and I would recommend that instead of Potatoes, Wheat should be the first crop, then Potatoes, and next Barley, which would not only clean the land but give a far better crop also of Barley and of the seeds after. Another system, which you will find among the farmers who occupy more largely, but which is still more objectionable than the former, is that of five Potatoes or Turnips, then Wheat, Barley, and Oats, or the Wheat, Barley, and Oats without the previous crop of Potatoes, or Turnips, Wheat, and two Oat-crops; the Oat-crop in either case seeded out, and generally cut for Hay the following year. This is done upon the manuring of the Potato, Turnip, or Wheat—a fact of the first crop. Now I ask can it be possible to pursue any system more ruinous than this? The land in this neighbourhood very, and consequently requires to be differently cropped; yet, let the land be what it may, never take three white crops in succession, nor two after a green crop. If you take two white crops following the green crop, you leave your land in a worse state than when you first broke it. I would recommend those who farm largely, and where there is a mixture of soils, wet and dry, to observe the following mode in preference:—On their dry land where they can grow Barley, to have Wheat, Barley, Turnips, and Barley, preparing for Wheat and Turnips; on those dry lands where they cannot grow a fair crop of Barley, they should have the intermediate crop Potatoes instead of Turnips, bearing in remembrance that all the lands that grow Barley in this neighbourhood are capable of growing Turnips. On those wet lands where the green crops cannot be grown with advantage, they should have Wheat and Oats, and allow the land to remain out two years. I could wish more farmers to adopt the system I have found indispensable in my own case; to take for instance 60 acres out of their estate, and crop it as I have mentioned, they would have 10 acres of Wheat, 20 of Barley, 10 of Turnips, 10 of seeds, and 10 of Lea, which would be put into Wheat in the autumn of every year. Were they to adopt this system they would find that the rusty appearance of the land in the spring of the year, so characteristic of this neighbourhood, would in a very short time disappear. Some persons I have observed in the last few years, have adopted a course of cropping, I suppose with a view to profit; I can only hope that for their own sakes they may not be deceived; all depends on the period they remain in their estates—that is, Wheat, Barley, and Turnips, Wheat, and Barley seeded. It would appear from this that farmers had no objection to see their land too free from weeds; for as soon as they succeed by judicious management in getting a good crop of Turnips, they seem to look with a jealous eye upon the good condition of their land, and again take the two white crops from it. I now come to the system adopted on the moors, which is Wheat, and two Oat crops, the last crop partially seeded, and the land allowed to remain out of tillage for years. I am not sure that there are not some farmers who believe that years rest in Grass is the cause of the land's increase in fertility; but I presume that every person who has studied the matter at all knows that land is enriched, not by rest, but by the quantity of food that cattle consume on it; or, in other words, the quantity of manure it returns. Here, then, there is a great field for improvement; and I am disposed confidently to assert, that were 1000 acres of waste or moor land which we have around us brought under a proper system of cultivation, the two great and desirable objects with which we set out would be attained—that of providing employ for our labourers, and food for our increasing population.

Miscellaneous.

Proper Time to Harvest Wheat.—Some experiments lately made indicate that there may be an improvement as to the usual time of securing the crop. By the Quarterly Journal of the Royal Agricultural Society, it appears that Wheat cut a fortnight before it was ripe produced an increased quantity and weight in flour and straw, with a better quality of bran. Mr. John Hannam of North Deighton, near Weatherby, in England, cut a sheaf in his field, August 4, 1840; the Wheat was then green—*i. e.* both the straw and ears were in full vigour and sap; the grain was perfectly formed; but the chaff so strongly adhered to it, that it was scarcely possible to separate them by friction in the hands; it was then plump, but no juice, that on the slightest pressure it yielded its milk. He let it stand in the field a fortnight, and then housed. On the same day this was done (August 18), he cut another. This, too, was yet green, or at least not ripe, or what is usually termed raw; the straw, though looking green, when closely examined was fast approaching to yellow, and a foot from the ground was quite yellow. The ears, also, were more open; the chaff of various shades of yellow and green; and the grain though soft and pulpy, yet not so full of fluid as before. In a fortnight after, the whole field was ripe, when he cut his third sample (Sept. 1). The same day he housed the second sheaf. This third was not so far ripe that the straw would break, and the ears curl, and the grain shake out; but it was in its usual state when reaping commences, when the straw is entirely yellow. This third sheaf was left (as in the case of the former ones), a fortnight on the field, and then carefully housed. From each sheaf 100 ears were selected and put away in a bag, preserving also the straw of each. On threshing them the following was the result:—

COMPARATIVE WEIGHT.

	Gross Produce.	Equal Measure.	Equal Number of Grains.
No. 1, cut August 4 (green)	756	568	192
No. 2, cut August 18 (raw)	736	540	224
No. 3, cut September 1 (ripe)	640	470	256

The comparative weight of the straw was:—

No. 1 (green)	540
No. 2 (raw)	478
No. 3 (ripe)	440

As to the value of the same, by the judgment of an extensive grower, the following was the result:—

No. 1, 61 shillings per quarter, or 1 dollar 672 per bushel.
No. 2, 64 shillings per quarter, or 1 dollar 76 per bushel.
No. 3, 63 shillings per quarter, or 1 dollar 764 per bushel.

A miller valued them at the same rate, with the exception of No. 2 at 63 shillings, and No. 3 at 61 shillings. Mr. Hannam's deductions are—that the Wheat reaped a fortnight before it was ripe has the advantage of the ripe in every point of view: 1st, in weight of gross produce, thirteen and one-fifth per cent.; 2d, in weight of equal measures, nearly one-half per cent.; 3d, in weight of equal number of grains, nearly two and one-fifth per cent.; 4th, in quality and value, above three

and one-fourth per cent.; 5th, in weight of straw, five per cent. That reaped a month before it was ripe has the advantage of the ripe 22 per cent. in point of straw; but in other points the disadvantage thus: 1st, weight of gross produce, eleven and five-thirteenths per cent.; 2d. weight of equal measures, rather more than one-third per cent.; 3d, weight of equal number of grains, better than 13 and one-tenth per cent.; 4th, quality and value, rather more than four-fifths per cent. The advantages, then, of cutting the crop a fortnight or so before it is fully ripe may be thus summed up: 1st, straw of better quality; 2d, a better chance of securing the crop: 3d, a saving in securing it. It is stated that, with regard to the crop of 1839 in England, the beginning of the reaping was late, and the result in the North of England was, that fully 75 per cent. of the whole Wheat crop was damaged. The saving of securing the crop is two-fold: there is less waste in reaping or from strong winds; and the expense of it is said to be less. Mr. Hannam tried another experiment, which showed a result in 100 lbs. of grain grown, as follows:—

	Flour.	Seconds.	Bran.
No. 1 was cut one month before fully ripe	75lbs	7lbs	17lbs
No. 2 was cut three weeks before fully ripe	76	7	16
No. 3 was cut two weeks before fully ripe	80	5	13
No. 4 was cut one week before fully ripe	77	7	14
No. 5 was cut when ripe	72	11	15

Thus, No. 3 gave more a bushel than No. 5, by six-and-a-half, and a gain of about 15 per cent. on the flour of equal measure of grain. In grinding, it was found that No. 5 ground the worst of all; there were a greater quantity of flinty particles which would not pass the bolt than in any of the others. The bran from No. 5 was coarse and heavy, while that from No. 3 was as "thin as a bee's-wing." He then sums up the advantages of cutting two weeks before it is fully ripe; 1st, there is a gain of 15 per cent. of flour, and equal measure; 2d, a gain in the weight of straw of 14 per cent.; 3d, a gain of 163 in the value of eight bushels, and a gain of about 583 on every acre of Wheat producing 28 bushels—his calculation being founded on the price of Wheat at that time in England. An experiment of cutting the grain ten days earlier than usual was also tried by a farmer in Michigan, on 60 acres—the berry being soft and in the milk; and the result was, that it yielded more flour and less bran than usual. Another advantage of early reaping is stated, on good authority, to be security from rust. A farmer is said to have tried an experiment on this subject. Finding one of his fields of Wheat in a very raw or green state was badly struck with rust, he determined at once to cut it, and did so amid the laugh of his neighbours, who thought him crazy. The fields adjoining suffered little from rust, and stood till fully ripe; yet at threshing, that which was first cut gave the finest Wheat and the best yield.—*Report of Commissioners of Patents, U.S.*

Mr. Borthwick, of Crookstons, Wood-thinner and Tree-pruner.—In the thinning of plantations, or the cutting of trees in any situation, it is always an object of attention, and often of difficulty, to take care that they do not injure other trees, valuable shrubs, or fences, &c., in their fall. In cutting out a Larch or Fir, for instance, from some surrounding Ashes, Elms, or Planes, if this consequence is not provided against, how often has one to regret the smashing of a fine hard wood tree, or valuable shrubs, or the breaking down of some expensive fence. To provide against such evils, means are taken to make the tree or trees that are cut fall in such a direction as to avoid them. If the trees are of any size, perhaps 20 or 30 years old, or even of less age and growth, it is generally found to be necessary to attach a rope or ropes to the upper part of the tree, to be held and pulled by one or more persons, according to circumstances, so as to cause the tree, when cut, to fall in the proper direction. To accomplish this purpose, it has been customary to employ climbers, or persons to go up the tree by means of a ladder, to fix the ropes; an operation which is attended with much labour, loss of time, danger to the persons employed, and inefficiently, from the difficulty of knotting the rope sufficiently near the top of a tree, which is necessary in order to increase the lever or purchase upon it. The inconveniences of these expedients led me to the invention and adoption of the following instrument:—It consists of a hook, the interior curve of which may vary in size from 4 to 6 or 8 inches in diameter. A ring, attached to it, must be of sufficient size to take in a rope of sufficient strength—say of what is called by the rope-makers from 9 to 18 threads. The handle or shaft, which must not be shorter than 15 or 18 feet, may be made of any light and strong wood, such as the shafts of hay-forks are made of. The hook is provided with a socket, into which the handle is fitted, but is not fastened by any nail. This simple apparatus is carried by the forester's assistant easily in his arm. A proper place, such as the insertion of a branch, is chosen for placing the hook round on the tree to be cut. The rope, which is spliced through the ring of the hook, being unrolled, the shaft is inserted in the socket of the hook, and being held in the hand of the forester or his assistant, the hook is held up by it to the part of the tree selected as most proper to pull from; the hook is put round this part, the handle is then withdrawn from the socket; and, by means of the rope, the hook is pulled firmly into its place by the assistant, who takes his proper position so as to guide the tree, and he sometimes to pull as the forester advances in cutting the stem of the tree; and, whilst he aids the cutter by widening the opening of the cut, draws the tree over, in the direction wished for, where it gently falls and crashes down, without injury to anything.—*Transactions of the Highland Society.*

Smut in Wheat.—Mr. Bevan made an extended course of experiments in England, which are found in the ninth volume of the "English Agricultural Magazine." He took both sound and smutty grain—the first being designated in the following table of results by the letter A, and the second by the letter B:—

	Number of smutted ears in a sheaves.		Bushels of good Wheat per acre.		Cwt. of Straw per acre.	
	A.	B.	A.	B.	A.	B.
Solutions of potash	1	81	31.6	13.6	38.6	29.1
Muriate of potash	3	212	20.2	10.1	36 0	21.1
Nitrate of potash, (saltpetre)	17	115	23,8	14.3	35.6	31.0
Soda	9	199	20.2	11.7	25.6	26.7
Muriate of soda, (com. salt)	—	290	24.6	14.5	41.5	33.8
Sulphate of soda, (Gl. salts)	12	241	21.6	12.3	31.1	27.6
Muriate of ammonia, (sal. am.)	1	180	19 8	17.8	35.4	30.2
Common soot	—	123	20.8	11.4	34.8	25.3
Lime saturated	—	2	21.9	12.4	38.7	25 9
Muriatic acid, (spirit of salt)	—	13.6	20.7	16.1	35.7	34.1
Sulphuric acid, (oil of vitriol)	—	—	20.4	17.8	35.4	34.1
Dry, in its natural state	—	6.923	20.3	14.7	35.7	31.0
Washed in common water	none	soon.	19.7	18.3	—	35.8

This course of experiments indicates lime-water to be the most effective. Putsche, in his "German Encyclopædia of Agriculture," gives the following as the receipt of M. Schraitz, of Düren, in the province of Juliers, in Prussia. So confident was M. Schraitz of its efficacy, that he offered a standing reward of a ducat for every head of smutted Wheat found in his field. For every 500 pounds of seed Wheat, take 1 pound of alum, 1 pound of copperas, ½ pound of saltpetre, ½ pound verdigris: pulverise these ingredients, and dissolve them in a sufficient quantity of boiling water. When the solution has become cold, add as much more water as will be required to moisten the whole thoroughly. The heap should be turned several times within the ensuing 24 hours, well mixed: it is then ready for seeding.—*Report of Commissioners of Patents, U.S.*

Selection of Seed Wheat.—An able writer in the Journal of the Royal Agricultural Society of England, in relation to the subject just mentioned, gives the following directions:—"In making a comparative trial with varieties of Wheat, it is necessary to select a portion of land uniform in texture, subsoil, and expense, and which for years has been cropped, manured, and laboured in all respects alike." "The lines of separation (of the varieties) ought to be well defined to guard against the mingling of the different varieties in the operation of sowing and harvesting. I recommend the seed to be deposited by a drill across the ridges, with a vacancy of three feet intervening between the varieties, and the seeding of all the land to be executed on the same day." "Respecting the quantity of seed, I can testify, from experience and observation, that even with the same variety of Wheat, any material difference in the state of the plant, all other circumstances being alike, influences the size of the ear, length of straw, and time of ripening, and the quantity and quality of produce, as well as the effects of red gum and mildew." He says, "a thin plant (*i. e.* a small number of young plants of Wheat standing on a given space of ground) generally enlarges the ears and corn, and retards the ripening, and aggravates the effects of red gum and mildew, while the straw is shortened both by a very thick and a very thin plant. It is therefore desirable, in comparative trials, to have all the varieties of the same thickness of plant." Another source of error which he mentions, is "the different propensity of different Wheats to tiller, or send out side shoots." He recommends, therefore, the trial Wheats to be sown "not by equal measures, but by measures calculated to contain the same number of seeds;" and also that the seeds should be sown "so thick as not to call forth the tillering propensity." He recommends, also, that journals of comparative trials should be kept, "embracing the appearance of the crops at all the different stages of growth, with the weather," or any other influences which may occur. A German writer of great celebrity further recommends that an estimate of the number of kernels of a kind be made by counting the number contained in a small measure, so as to give still greater accuracy to experiments made on this subject. The following are considered, by an authority on this subject in our own country, as suitable characteristics to be taken into consideration in selecting Wheat for our crops:—"1st. The general hardiness of the plant, and capability to resist the Hessian fly, or throwing out by frost and winter-killing, rust, and mildew. 2d. A good strong upright stalk, with just enough straw for the object, and no more. 3d. No beard is desirable; a head filled and heavy, and retaining the grain as long after it is ripe as possible. 4th. A predisposition to tiller well. 5th. A plump full berry, capable of yielding a large quantity of white flour, with a large proportion of gluten, and as little bran as possible."—*Report of Commissioners of Patents, U.S.*

Notices to Correspondents.

Analysis.—*J. Brewing.*—We cannot undertake analysis of soils. There are many gentlemen to whom you may apply, as an inspection of our advertising columns will inform you.

Cabbages.—*North Earle.*—The Early York, if sown in a bed now, and transplanted when ready in autumn, will be fit at the time you name.

Disease in Cows, &c.—*J. K* says that he has had four cows dead lately, one later in the chest and a decay in the lungs; and three calves, of a swelling in the knee and other joints. The cause of death in the cows was in all probability the dreadfully fatal epidemic called *Pleuro-Pneumonia*, which word signifies inflammation both of the substance of the lungs, and also the membrane covering them and lining the interior of the chest. The actual cause of this fatal disease is unknown, but it is doubtless produced by some poisonous gases or effluvia in the atmosphere. Cattle in good condition are more likely to be attacked than others, and in them it is more likely to be fatal. It is believed to be more prevalent in high and inland localities, where the air is keen and bracing, than where the atmosphere is milder. When the disease is thoroughly established, there is but a poor chance for curative treatment. The conflagration is so extensive and rages so fiercely that we cannot put it out. If one half the previous value of the animal can be realised by the carcase, the butcher's knife will be the best resource. In applying a remedy, it is all-important to commence early, when a slight cough or the least impairment of health is perceived. We should then bleed freely, give a dose of Epsom salts (a pound with two drachms of ginger), blister the sides, and put setons in the brisket. If this is delayed till a certain stage, the bleeding will do harm instead of good. The salts and the setons will be advisable as preventives, and the latter should be stimulated with hellebore ointment. If the disease in the calves is confined to the joints and limbs, and the chest is not affected, it is that which is locally denominated joint-evil, and in various districts receives different names. If, however, the chest is affected as in the former disease, we have reason to fear it must be connected with it. If the former disease, it is an inflammation of a rheumatic character of the membrane lining the joints, sheaths of the tendons, and fibres of the muscles, and often flies from one part to another, and baffles all treatment. It is probably owing to exposure to cold and want of shelter, and if the young animal has been very badly kept in the winter, it is more likely to be attacked by the disease the succeeding spring and summer. As to treatment, give a mild purgative, and follow it by ginger, gentian, and spirit of nitrous ether—a quarter of an ounce of each in a pint of warm ale. Rub turpentine and oil, or a stronger stimulant, on the affected parts, and if the pulse feels strong, bleed. Warmth, shelter, attention, and care, are indispensable.—*W. C. S.*

Drilling Machines.—*A. S.*—We know of none answering your description. You had better apply to some first-rate agricultural implement maker. Of course we cannot recommend.

Feeding Cattle.—*A. O.*—Cattle may doubtless be fattened on oil-cake and straw; but the profitableness of your scheme depends so much on the price you would be able to get for your manure, and upon your skill in the purchase and sale of stock, that, in our ignorance of these, we cannot answer your question.

Grass.—*Lumpy.*—Sow early in spring, Alopecurus pratensis 14 lbs., Avena pubescens 4 lbs., Dactylis glomerata 5 lbs., Festuca duriuscula 2 lbs., F. pratensis 2 lbs., Lolium perenne 12 lbs., Poa pratensis 1 lb., Medicago lupulina 1 lb., Trifolium pratense 4 lbs., T. repens 5 lbs., and Rye 1 bushel, per acre. These are the kinds and quantities recommended by Lawson as seed on light soils for permanent pastures. You will have to sow only those in which your pasture is deficient.

Guano.—*J. B. B.*—It will keep uninjured if kept in a close apartment. Your plant is Melilot Trefoil—Melilotus officinalis.——*T. White.*—Peat charred mixed with guano will tend to hinder the escape of ammonia: peat ashes will not do so; indeed, if they were mixed when fresh, they might expel the ammonia. The use of guano will not put an end to that of lime; the latter will be required just the same as before. Possibly it may be better to spread the super-phosphate of lime on the young Wheat in spring than to plough it in with the seed in autumn; it will not be so liable to waste. We should be glad to know your experience of this manure.

Liquid Manure.—*R. S. T.*—Throw all this from the house into the tank. You may add soot to it; but the cheapest way is to pump the whole over compost heaps of manure, rubbish, soot, &c. The drainings of your yard are valuable as liquid manure.

Suffolk Duns.—A wishes that some of our Suffolk correspondents would inform him in what the excellent milking properties of the Suffolk Duns consist—whether in affording large quantities of milk or butter, or both combined? Whether they have ever been tried at a distance from their own county, and found to retain these valuable properties as an object? Some book authorities he finds considerable diversity of opinion to exist.

Tanks.—*R. B.*—Dig a cylindrical hole, say 10 feet deep and 10 feet in diameter, making the bottom basin-shaped; surround it at bottom with brick paving, at the sides with an ordinary stone or brick and mortar wall, carrying the wall down behind it, and at the top with a flat stone and lime stone, leaving an opening by which to enter it, and a sufficient number of small openings round the edge for the liquid to enter it. A pump, communicating by means of pipe and rose, within 6 feet of the bottom, is wanted to complete the work.

White Beetroot.—*A Reader* asks for information about the culture of White Beetroot for sugar, and how far it is likely to succeed under *great heat*, where the soil, however, is rich and a supply of water for irrigation attainable.

Winter Tares.—*No. 5.5.7.*—If they are sown in about four weeks' time, we apprehend you may expect a crop in June. The weight of green food it will afford you depends so much on the quality of the land that we can hardly answer your question: it will probably be from 7 to 10 tons per acre.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Aug. 12.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 0 to 4s 0		Beas Downs & half-breds	3s 10 to 4s 0		
Best Short Horns	2 8	3 10	Best Long-wools	3 6	3 10	
Second quality Beasts	2 6	2 6	Ewes and second quality	3 4	3 6	
Calves	3 8	4 0	Lambs	4 0	4 6	
Pigs	3 4	4 0				

Beasts, 741; Sheep and Lambs, 21,000; Calves, 282; Pigs, 220.

The supply of Beasts is much shorter to day, especially of the best qualities, which experience a rise in price of fully 2d per 8 lbs from last Monday's quotations: the Short-horns are selling much more readily at our top quotations than on Monday last, but very few make anything over 4s 10d per 8 lbs; there is a heavy trade amongst the middling qualities, although they are rather more readily disposed of than of late. There is also rather a less quantity of sheep, but the number is still considerable; trade is very dull at about last Monday's prices for the best qualities: Ewes and plain Sheep, which are plentiful, do not find so ready a sale as they have done, and make rather less money. Lamb trade is very heavy. Veal trade continues steady. Pork is a little more in demand.

FRIDAY, Aug. 16.

The trade for the best Beef is about the same as on Monday; the supply is moderate; some of the best Scots make 4s 2d, but the more general price is 4s, and Short-horns 3s 10d per 8 lbs: middling qualities are still very heavy on hand, and make from 3s to 3s 4d. The Mutton trade is rather improved, there being a good clearance at the dead market, and rather a shorter supply here this morning; there is nearly 2d per 8 lbs the advance on the best qualities; second-rate remain about the same. Lamb is no better; the price continues from 4s to 4s 8d, with very few at the latter. Calves are a slow trade, but some of the nicest still make nearly 4s 4d. Pork remains steady, at from 3s 4d to 4s.

Beasts, 781; Sheep and Lambs, 1960; Calves, 340; Pigs, 280.

41, West Smithfield.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, Aug. 13.

Prime Upland Hay	100s to 108s		Clover	100s to 120s	Straw	28s to 32s
Inferior „	80	95	„ New „	—		
New Hay „	80	95				

Jesse Cooper, Salesman.

CUMBERLAND MARKET, Aug. 15.

Superior Old Hay	100s to 110s		Superior Clover	110s to 120s		
Inferior „	90	96	Inferior „	100	110	Straw 28s to 32s
New Hay „	90	100	New Clover	100	110	

Joshua Baker, Hay Salesman.

WHITECHAPEL, Aug. 16.

Fine Old Hay	90s to 98s		Old Clover	120s	130s	Straw 28s to 30s
New Hay „	75	88	New Clover	90	110	

WOOL.—British, Friday, Aug. 16.

Our English Wool Market remains unaltered. The demand is good, but prices have not advanced.

	per lb.				per lb.	
Long-woaled Wethers	1s 0d	to 1s 1d	Southdown Ewes		1s 1d	to 1s 2d
Do. Hoggets	1 1	1 2½	Kent Fleeces		1 1	1 2½
Southdown Fleeces	1 0	1 1				

James Parker, Wool Broker.

COVENT GARDEN, Aug. 17.—The market has been well supplied during the week with fruit and vegetables of almost every kind; the latter are rather improving. Pine apples are good, and quite sufficient for the demand. Amongst Grapes are excellent bunches of White Muscat; and Black Hamburghs, in particular, are good. Peaches and Nectarines are rather scarce; forced sorts are nearly over, and those from the open wall are not yet abundantly supplied. Apricots are plentiful, the best bringing about 3s. per dozen. Orleans, Damask, and Violet Plums are abundant. A considerable quantity of Jargonelle and Windsor Pears are also in the market. Among Apples, we noticed good specimens of Dutch Codlin and Kerry Pippin; other sorts are also good and plentiful. The best Morello Cherries are selling at about 2s. 6d. per half-sieve. Gooseberries are nearly over, and Currants are becoming very scarce. Filberts are rather on the increase. Of Vegetables, Cauliflowers are good, and sufficient for the demand. Cabbages and Turnips are improving. French Beans are good, and very abundant, and there is also a good supply of Windsor Beans. Onions are plentiful; Peas are becoming less abundant. Carrots are good, and Shallots are sufficient for the demand. Salading and Herbs of every kind are abundant. Cut Flowers are chiefly composed of Ceanothus azureus, Hypocrite zonalis, Tallow and Perpetual Roses, Sweet Peas, Heaths, Verbenas, Fuchsias, Scarlet Pelargoniums, Gardenias, Pinoteas, and Carnations.

FRUIT.

Pine Apple, per lb.	Currants, per half-sieve, 2s. 6d. to 3s. 6d.
Grapes, Hothouse, per lb. 2s. to 3s. 6d.	Gooseberries, per half-sieve, 1s. 6d. to 2s.
— Spanish, per lb. 1s. to 1s. 6d.	Filberts, per 100 lbs., 20s. to 30s.
Melons, each, 2s. to 3s.	Oranges, per dozen, 1s. to 2s.
Peaches, per dozen, 4s. to 6s.	— per 100, 6s. to 14s.
Apricots, per doz. 2s. to 3s.	— bitter, per 100, 10s. to 14s.
Plums, per half sieve, 2s. 6d. to 3s.	Lemons, per dozen, 1s. to 2s.
— Orleans, per half-sieve, 1s. to 2s.	— per 100, 4s. to 10s.
— Green Gages, 4s. to 6s.	Almonds, per peck, 6s.
Apples, Pears, per bushel, 4s. to 6s.	Sweet Almonds, per lb., 2s. 6d.
— Kitchen, 2s. to 3s.	Nuts, Hazelnuts, 3s.
Pears, Bon Chretien, 2s. to 3s.	— Brazil, 1s.
Cherries, Wall, per lb., 1s. to 1s. 6d.	— Cob, 1s.
— Morello, per half-sieve, 1s. to 2s.	

VEGETABLES.

Cabbages, per dozen, 1s. to 2s. 6d.	Leeks, per bun., 4d.
Cauliflowers, per doz., 2s. to 3s.	Shallots, per lb., 6d. to 8d.
Sorrel, per half-sieve, 2d. to 3d.	Garlic, per lb., 6d. to 8d.
Artichokes, per doz., 1s. to 2s.	Onions, per bunch, 2d. to 3d.
French Beans, per half-sieve, 1s. 6d. to 2s.	— Spanish, per bushel, 1s. to 2s.
Potatoes, New, per cwt., 3s. to 3s. 6d.	Shallots, per lb., 6d. to 8d.
New Turnips, per bunch, 3d. to 4d.	Tomatoes, per punnet, 1s. to 1s. 6d.
Peas, per bushel sieve, 2s. to 3s.	Capsicums, per score, 6d. to 1s. 6d.
Beans, per bush. sieve, 1s. 6d. to 2s. 6d.	Celery, per bunch, 1s. to 1s. 6d.
Red Beet, per doz., 1s. to 2s.	Mushrooms, per pottle, 6d. to 1s.
Carrots, 4d. to 6d.	Small Salads, per punnet, 2d. to 3d.
Basil, per bunch, 3d. to 4d.	Mushrooms, per 12 pun. 3s. to 6d.
Horse Radish, per bundle, 3s. to 4s.	Tarragon, per doz. bunches, 1s. to 2s.
Savory, per bunch, 2d. to 3d.	Asparagus, Cayan, per bunch, 3d. to 6d.
Cucumbers, Frame, each, 6d. to 1s.	— Grass, per bunch, 2d. to 3d.
— Ridge, each, 2d. to 3d.	Chervil, per bunch, 2d. to 3d.
Vegetable Marrow, per doz. 4d. to 1s.	Chervil (turnip rooted), 3d. to 4d.
Spinach, per sieve, 1s. 6d. to 2s. 6d.	

HOPS, Friday, Aug. 16.

Our Market continues very active, and prices advancing. The Duty has fallen to 100,000*l.*

Perryman & Sons, Hop-Factors.

MARK-LANE, MONDAY, Aug. 19.

The supply of Wheat from the home counties this morning was the smallest received all the year, including a very few samples of new, which were good, but some, apparently, rather coarse—the quantity was too small to form a correct opinion, either of its general quality or value; old brought 1s. to 2s. over the prices of this day se'nnight. Business in Foreign was not extensive, being restricted by the advanced prices, at which it was generally held, and it must be noted 1s. dearer than on Monday last.—Barley and Peas remain unaltered; the former meets rather more inquiry.—Beans are also more in demand.—Oats sell more freely, Irish at 6d. and Foreign 6d. to 1s. above last week.

FRIDAY, Aug. 16.

Having had a great deal of rain from Monday to Wednesday, and during the Market of that day, prices of English Wheat advanced 1s. per qr., and at the close a rise of 2s. upon our quotations was pretty generally obtained on Foreign. Although the wet weather continued here yesterday, the accounts from the country this morning lead us to believe that no material injury has yet been sustained by the Wheat still in the fields, nevertheless, the few sales made at the opening of the Market were about 1s. over the rates of Wednesday, but the day proving fine, very little business was subsequently transacted.—Barley, Beans, and Peas fully maintain their late value, and Oats must be written 6d. to 1s. dearer.

ARRIVALS THIS WEEK.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS and Co., Architects, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL-ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to James Clark, 24, Billiter-street.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; Wm. J. MYERS AND CO., LIVERPOOL;

And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.

47, Lime-street, Aug. 15, 1844.

GYPSUM, &c.—Pure Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.; also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.

Synopsis of Prices, and mode of use, on application.

Mark Fothergill, 10, Upper Thames-street.

TO FLORISTS AND ADMIRERS OF FLOWERS.

BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

This preparation is peculiarly adapted for the development of Flowers, furnishing them with the materials (in a soluble form) out of which they weave their delicate tissue and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing-room.—Price 1s. 6d. per quart Bottle, and may be had of Wm. Jackson, late Geo. Butler, 93, Cheapside, corner of King-street, and most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas-st., Stamford st., Blackfriars-rd.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculture generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 22 inches wide, at 1d. per foot, super. A discount to the trade. Thos. J. Crudgon, 5, Ingram court, Fenchurch-st., London.

ASPHALTE.—BROWN OIL VARNISH, BLACK VARNISH PAINT.—Asphalte in a pure state, without grit, 3s. per cwt., in casks 2 cwt. each, for forming or improving garden walks, terraces, court yards, stables, granite floors, roofs, or for applying to damp walls. Brown Oil Varnish for varnishing gates, outhouses, fences, &c., 8d. per gallon—it dries very quickly. Black Varnish Paint for outhouses, fences, &c., 8d. per gallon.—R. Richardson, Net and Tent maker, 91, Tonbridge place, corner of Judd-street, New Road, London.—Pitch 3s. per cwt. Stockholm Tar, &c.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water-courses. In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. Bailey Denton has arranged with an eminent London Mathematical Instrument Maker to make them in any number required. Price 30s.

This Level is as accurate as a spirit-level, and so simple, that the workman unable to read can use it with facility. When closed it forms a walking-staff.

Orders addressed to Mr. Dawson, Land Agent, 9, Gray's Inn-square, will insure a perfect instrument.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet-street.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon-Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Sashes and Lights complete, from 14s. 6d. Garden Lights made and glazed from 1s. per foot, at Jas. Watt's Sash Manufactory, Claremont-place, Old Kent-road. *** Reference given.

HATCHER'S BENNENDEN TILE-MACHINE, Manufactured and Sold only by COTTAM and HALLEN, Engineers, Agriculture Implement Makers, &c., 2, Wimbledge-street, Oxford-street, London.

This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With this amount of labour, the product of a day of 10 hours is as follows, viz.:—

1 inch diameter of Tile, 3 inches diameter of Tile, 5,000
1½ " " 3,600
2 " " 3,200

The Machine is movable down the drying-sheds, so that it requires no extra hand to carry the Tiles, nor are shelves required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Gravesend, Kent. No charge made for Patent dies or moulds. The purchase of the Machine includes free use of it.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of reaching thoroughly into the dividing of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at Metcalfe's Sole Establishment, 130a, Oxford-street, one door from Holles-street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steamship, June 6*, 1841.—The cabin of the Great Western has been regularly supplied with Lea & Perrins's Worcestershire Sauce, which is admitted by every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a piquant relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) James Hosken."

"One of the most piquant, ingenious, of the luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long-established favourites, more wholesome, and of less cost."—*Naval and Military Gazette, April 6, 1842.*

Sold Wholesale by the Proprietors, Messrs. Lea and Perrins, Worcester; Messrs. Barclay, Fleet-street, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the most venders of Sauces.

HORIZONTAL WATCHES, very flat.—A. B. SAVORY and SONS, Watchmakers, 9, Cornhill, London, opposite the Bank. Price, in silver cases, three and a half guineas each; or in gold cases, six guineas each. These Watches are accurate and durable, the horizontal escapement being peculiarly suited to combine those important requisites. They are jewelled in four holes, and contain going wallet being wound. A twelve month's warranty given with each.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, City, London.—Mr. J. A. Meyer, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Breweries, Chester, and Gallery Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., 50s., and 100s., each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

BRIGHT'S CUSTARD COMPOUND.—The ORIGINAL VEGETABLE PREPARATION, for making custards without eggs. Patronised by the Royal family, Nobility, and Gentry, with the approval and testimony, amongst many others, of the COOKS to SIX CROWNED HEADS. Sold in boxes at 1s. and 2s. each. Manufactory, 5, Holland-street, North Brixton, Surrey. Wholesale of all respectable houses, and retail by upwards of 1000 chemists, confectioners, grocers, Italian Warehousemen, &c., throughout the United Kingdom. Caution—Beware of imitations, and observe on all and not the signature of the Inventor, John Bright.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, Lambeth Pottery, High-street, Lambeth, London.

D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone of Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed.

THE PUBLIC compare the quality of the EAST INDIA TEA COMPANY'S TEAS with their advertised prices and marvel (it would indeed appear marvellous) how Six Pounds of really Good Tea can be sold for 17s. The simple fact is, that the Company treat all alike, and give the private consumer all the advantages of the public dealer.—Offices, No. 9, Great St. Helen's Churchyard, Bishopsgate Street.

EKERT'S HERBAL, VOLUME.

Volume.

FEATS ON THE FJORD: a Tale of Norway. By HARRIET MARTINEAU. A new Edition.
London: Edwards Moxon & Co., 64, Lidgate-street.

Complete in one Vol., price 21s., cloth,

THE FLOWER-GARDEN OF ORNAMENTAL PERENNIAL HERBACEOUS AND SHRUBBY PLANTS, with Directions for the Cultivation of nearly five Hundred Perennial Herbaceous Plants, or such as die down in the winter, to appear again in the spring—including a large number of showy flowers and gracefully shrubs, but which will grow freely in any garden. By Mrs. LOUDON.

London: Published by WILLIAM SMITH, 113, Fleet-street, of whom may be had, by the same Author,

THE FLOWER-GARDEN OF ORNAMENTAL ANNUALS; cloth, price 2s. 6d.

THE FLOWER-GARDEN OF ORNAMENTAL BULBOUS PLANTS; cloth, price 2s. 6d.

WITH THE APPROVAL OF THE LORDS COMMISSIONERS OF HER MAJESTY'S TREASURY.

COMPLETION OF THE ZOOLOGY OF THE BEAGLE.
Just completed in Five Vols. bound in cloth, or in half Morocco or Russia, at a small addition to the price,

THE ZOOLOGY OF THE VOYAGE OF H.M.S. BEAGLE, under the command of Captain Fitzroy, R.N., during the years 1832 and 1836. Edited and superintended by CHARLES DARWIN, M.A., F.R.S., Naturalist to the Expedition. Containing highly finished representations of the most novel and interesting objects in Natural History, collected during the voyage of the Beagle, with descriptive letter-press, and an account of the habits and ranges

CONTENTS OF THE VOLUMES.—Land Mammalia, by Richard Owen, Esq., F.R.S., plain plates, 1l. 14s.—Mammalia by R. Waterhouse, Esq., coloured, 1l. 5s.—Birds by John Gould, Esq., F.L.S., coloured, 3l.—Fish, by the Rev. Leonard Jenyns, M.A., F.L.S., plain plates, 1l. 18s.—Reptiles, by Thomas Bell, Esq., F.R.S., F.L.S., plain plates, 1l. 5s.

Each Volume is complete in itself, and may be had separately

GEOLOGICAL OBSERVATIONS made during the VOYAGE of the BEAGLE in Three Parts.
By CHARLES DARWIN, M.A., F.R.S., &c.
Just Published in 1 vol. 8vo, price 15s. cloth

PART I.—ON THE STRUCTURE AND DISTRIBUTION OF CORAL REEFS.
Just Published,
PART II.—ON THE VOLCANIC ISLANDS OF THE ATLANTIC AND PACIFIC OCEANS.
(Together with a brief Notice of the Geology of the Cape of Good Hope and of part of Australia.)
PART III.—ON THE GEOLOGY OF SOUTH AMERICA.
London: SMITH, ELDER & Co., 65, Cornhill.

Just Published, Second Edition, revised, with Introductory Comments upon certain Criticisms that have appeared on the Work, in 2 volumes, post 8vo., with a Portrait,

A NEW SPIRIT OF THE AGE. Containing Critical Essays and Biographical Sketches of Literary and other Eminent Characters of the present time.
Edited by R. H. HORNE, Esq.
London: SMITH, ELDER, and Co., 65, Cornhill.

IMPORTANT TO AGRICULTURISTS.
In the Press the Second Edition,

A PRACTICAL ESSAY, and Instructions for the Use of Guano as a Manure, generally arranged for all Soils and Crops, Horticulture, &c., with a Table of 500 Tested Manures and Results from the earliest introduction of Guano into the United Kingdom, including the Reports and Progress of the Royal Agricultural Meeting at Southampton, and the Highland and Agricultural Society of Scotland, down to the present time; with proper Rules for the Application of Guano to every Farm, to be applied with Sowing and Drilling of Wheat, also for Grass and Meadow Land in the autumn, with Instructions to purchase and secure pure Guano, and to ascertain if genuine or spurious, and a remedy for retaining its full power and strength any length of time out of the soil

Applications to the Author only can be supplied, and all letters to be post paid, inclosing 1s. 6d.; including a Treatise on Turnips, 2s.; and the work will be posted pre paid

N.B.—Attested genuine AFRICAN GUANO, as imported on ship at Liverpool, 9l. 15s., and Spring delivery for 1845 9l. per ton; payment by approved Bills at three months, on delivery.—Direct J. R. SHARPLES, Land Surveyor, City of Chester

Just published the Thirteenth Edition, price 2s 6d., free by post 3s 6d.,

THE SILENT FRIEND on NERVOUS DEBILITY, CONSTITUTIONAL WEAKNESS &c. By E. and L. PARRY and Co., 8 Crane, London. Published by the Authors, and sold at their residence, 48 Bishopsgate Without, Strange, 21, Paternoster row, Sutton, 10, Chancery lane, Tucker 1, Milford-lane, Strand; Ward, 161 Strand opposite Exeter Hall; Gorham, 138, Tottenham st., Purkiss Compton & Soho Willson, 256, Oxford st. (two doors from Argyll st.) London. The Cordial Balm of Syriacum is a stimulant and restorator in all Bronchial complaints. Nervous Debility, Indigestion, Asthma, and Consumption, are gradually and imperceptibly removed by its use and the whole system restored to a healthy state of organization. Sold in bottles, price 11s and 33s. Parry's Pectoral Aperient Pills have long been used as the most certain remedy for Bronchial Complaints of every description, Eruptions of the skin, Pimples on the Face, and other disagreeable affections, the result of an impure state of the blood. These Pills are perfectly free from mercury and other deleterious drugs, and may be taken with safety without the restriction of a change of diet from business, and can be relied upon in every instance. Sold in boxes, at 2s. 9d., 4s. 6d., and 11s., by all Medicine Venders.

Messrs. PARRY and Co. may be consulted daily at their residence, 19 Brewers street, Oxford street, from 11 till 2, and from 6 till 8.—On Sundays, from 10 till 12.

On the 1st September will be published, Part I., price 2s 6d., of

BRITISH WILD FLOWERS.
By MRS LOUDON.
With three Coloured Plates in each Number. Demy 8vo.

This work will only include those British Plants which are of some common and general use, as it is intended principally for the use of ladies in their country walks, who may wish to know the names of those they meet with in the fields and hedgerows, and some particulars respecting them. As the work is to be of quite a popular character, the English names of the plants will be made the most prominent; but, in order to render it as generally useful as possible, especially to young persons, the most striking botanical characteristics of each plant will be explained in such a manner as to be perfectly comprehensible to every reader.

The form of the work will be that of the "Ladies' Flower Garden," and it is intended to comprise the whole in one thick volume of about twenty Numbers

London: WILLIAM SMITH, 113, Fleet-street.

WORKS PUBLISHED FOR
TAYLOR AND WALTON,
28, UPPER GOWER STREET.

CHEMISTRY APPLIED TO THE ARTS.
Now ready, Vol. I., 8vo., cloth, of

PARNELL'S APPLIED CHEMISTRY; in MANUFACTURES, ARTS, and DOMESTIC ECONOMY
Illustrating
Glass, Starch, Tanning, Chromiums, Prussic and the Hydrocyanic Legumen, Resin, Sulphur and Sulphuric Acid, Soda,
Lately published,
PARNELL'S APPLIED CHEMISTRY, Vol. I., Price 12s.
CONTENTS:
Preliminary Observations, Gas Illumination, Preservation of Wood, Dyeing, and Calico Printing.

THE STEAM-ENGINE, STEAM NAVIGATION, AND RAILWAYS.
One vol. 8vo, with 167 Engravings on Wood, 12s., cloth,
THE STEAM-ENGINE EXPLAINED and ILLUSTRATED. With an Account of its Invention and progressive Improvement, and its Application to Navigation and Railways, including also a Memoir of Watt. By Dr LARDNER. Seventh Edition; with a Portrait of Watt.

CONTENTS:
Preliminary Matter—Engines of Savery and Newcomen—Early Career and Discoveries of James Watt—Exposition of Physical Principles—Further Discoveries of Watt—Watt's Engines—Double acting Engine—Boilers and Furnaces—Life of Watt
LOCOMOTIVE ENGINES ON RAILWAYS
High pressure Engines—Effects of Railway Transport—History of the Locomotive Engine—Liverpool and Manchester Railway—Experimental Trial Progressive Improvement of Locomotive Engines Detailed Description of the most improved Locomotive Engines—Dr Lardner's Experiments on the Great Western Railway—Methods of surmounting steep inclinations.
LOCOMOTIVE ENGINES ON TURNPIKE ROADS
Railways and Stone Roads compared—Gurney's Steam Carriage—Two methods of applying Locomotive Engines upon common Roads—Hancock's steam Carriage.
STEAM NAVIGATION.
Form and Arrangement of Marine Engines—Common Paddle-wheel—Improved Efficiency of Marine Engines—Iron Steam vessels—Steam Navigation to India
AMERICAN STEAM NAVIGATION
Steam Navigation first established in America—The Hudson navigated by Steam—Fulton and Improvement of River Navigation—American steamers—Difference between them and European steamers—Steam Tugs

CHEMICAL ANALYSIS.
In 1 vol 8vo, with Diagrams on Wood, price 10s 6d cloth,
ELEMENTS of CHEMICAL ANALYSIS, INORGANIC and ORGANIC. By EDWARD ANDREW PARNELL, late Assistant Lecturer on Chemistry in the Medical school of St Thomas's Hospital.
"We have perused this interesting volume with great satisfaction and have no hesitation in recommending it strongly as a safe and valuable guide in conducting the intricate and perplexing operations of analytical chemistry."—*Medico-Chir. Review*, Jan 1844.

LIEBIG'S AGRICULTURAL CHEMISTRY.
Third Edition, with large additions and very numerous alterations, 8vo, 10s 6d
CHEMISTRY in its APPLICATIONS to AGRICULTURE and PHYSIOLOGY By JUSTUS LIEBIG, M.D. Ph.D., F.R.S., Professor of Chemistry in the University of Giessen Edited, from the Manuscript of the Author, by LYON PLAYFAIR, Ph.D.
"—a book infinitely superior to its predecessors, and to a very considerable extent unlike them"—*Gardeners' Chronicle*

LIEBIG'S ANIMAL CHEMISTRY.
Second Edition, 1 vol. 8vo, price 9s 6d.,
ANIMAL CHEMISTRY, or, CHEMISTRY in its APPLICATIONS to PHYSIOLOGY and PATHOLOGY By JUSTUS LIEBIG M.D., Ph.D., Professor of Chemistry in the University of Giessen Edited, from the Author's Manuscript by WILLIAM GREGORY, M.D., Professor of Chemistry in the University of Edinburgh
"While we have given but a very imperfect sketch of this original and profound work, we have endeavoured to convey to the reader some notion of the rich store of interesting matter which it contains The chemist, the physiologist, the medical man, and the agriculturist, will all find in this volume many new ideas and many useful practical remarks. It is the first specimen of what modern Organic Chemistry is capable of doing for Physiology, and we have no doubt that from its appearance Physiology will date a new era in her advance"—*Quarterly Review*, No 139.

LIEBIG'S CHEMICAL LETTERS.
Second Edition, fcap 8vo, 4s 6d
FAMILIAR LETTERS on CHEMISTRY, and its Relations to Commerce Physiology, and Agriculture By JUSTUS LIEBIG, M.D., Professor of Chemistry in the University of Giessen Edited by JOHN GARDNER, M.D., Member of the Chemical Society
"That the public will discover its merits, and that it will find its way into the drawing room as well as the library, and be equally prized by the advanced man of science and the student, we venture to say is certain, and it must increase the respect entertained for Chemistry wherever it is read"—*Chem. Gazette*

MULLER'S PHYSIOLOGY.
2 vols 8vo, each volume 20s
ELEMENTS of PHYSIOLOGY By J. MULLER, M.D., Professor of Anatomy and Physiology in the University of Berlin Translated from the German, with Notes, by WILLIAM BALY, M.D., Graduate in Medicine of the University of Berlin Illustrated with Steel Plates and very numerous Wood Engravings.
"We do, however recommend it very earnestly, and we have no hesitation in saying that it will supersede all other works as a text-book for lectures, and one of reference for students. It steers a middle course between the unpardonable brevity of many of our modern works, and the pretension and metaphysical jargon of Burdach"—*Med. Chir. Review*, April, 1844.
"*" Subscribers are requested immediately to complete their Copies.

MR. LOUDON'S NEW WORK ON THE TREE.
This Day is published, 12mo, 4s. cloth,
A DESCRIPTIVE ACCOUNT OF A NEW METHOD of PLANTING and MANAGING the ROOTS of GRAPE VINES. By GEORGE MEASON, Author of "A Treatise on the Cultivation of the Grape Vine on Open Walls."
London: LONGMAN, BROWN, GREEN and LONGMANS.

Yorkshire Agri Society - 580 c

RAY SOCIETY, instituted 2nd February, 1844.—This Society has been formed upon the principle of the Parker, Camden, Sydenham, and other Societies, for the purpose of securing to those attached to the study of Natural History, such Works on the various branches of Zoology and Botany as could not be obtained by other means; and will consist of original works; of new editions of works of established merit; of rare tracts and MSS.; and of translations and reprints of foreign works. Every subscriber of one guinea annually will be considered a member of the Society, and will be entitled to a copy of every work published by the Society. The Council have great pleasure in stating that the number of Members already exceeds 300, and beg to call the attention of their friends to the necessity of sending in their names as early as possible, in order that they may be enabled to determine the number of copies of their works which they ought to print. The Council hope to publish two volumes before Christmas, the first of which will consist of translations from the German and Italian, of Reports on the progress of Zoology and Botany during the last few years.

Communications on the business of the Society are requested to be addressed to the Secretaries, Dr. George Johnston, Berwick-upon-Tweed, and Dr. Lankester, Golden-square, London. Subscriptions to be sent, by post-office order or check, to the Treasurer, J. S. Bowerbank, Esq., 45, Park-street, Islington.

GEORGE JOHNSTON, M.D.
EDWIN LANKESTER, M.D. } Secretaries.

INGA PULCHERRIMA. (Figured in "Paxton's Magazine of Botany" for August, 1844.)—Fine Plants of this extremely elegant and beautiful Exotic, with most of the other new and rare Plants of the season, may be obtained of the undersigned, at the following low prices:—

Inga pulcherrima, 7s. 6d.
Achimenes picta, 10s. 6d.
Æschynanthus Horsfieldii, 7s 6d
Amycia zygomeris, 7s. 6d.
Clerodendron splendens, 10s. 6d
" squamatum, 5s.
Hindsia, or Rondeletia longiflora, 15s.
Epacris campanulata rosea (the finest selected from 1000 seedlings), 7s. 6d.
Habrothamnus elegans, 15s.
Tremandra Hugelii, 10s. 6d. to 21s.
Veronica speciosa, 5s. to 15s.
Erica elegans, fine and healthy, 15s., 24s., and 30s. per doz.
Drymonia punctata, 3s. 6d.
Phlox Van Houttei, (flowering plants), 2s.
Spiræa Reevesiana, 5s.
Viburnum cotonifolium, 3s. 6d.

Also the following, in collections:

100 Cape Ericas of 100 distinct sorts, (including many fine sorts) 5l.
12 Epacrises of 12 distinct sorts, (including Campanulata rosea) 21s.
12 Azalea indica, of 12 distinct sorts, (including fulgens) 21s

THOMAS JACKSON, Kingston Nursery, Surrey, August 23.

MESSRS. J. AND H. BROWN are now sending out to any part of the Kingdom the following very desirable plants:—

The beautiful new Lilium lancifolium album and punctatum, flowering plants, 3s. 6d. and 5s. each; very strong plants, 25s. each; good bulbs that will bloom next season, 18s. and 24s. per dozen.
Lilium venustum, sanguineum, longiflorum, and eximium, 12s. per dozen.
Chrysanthemums, newest and best varieties, 9s. p. doz., sent post-free.
The best new Fuchsias of 1844, 18s. per dozen; other approved kinds, 6s. and 9s. per dozen.
Bouvardias, 4 varieties, 6s. per doz.; strigosa, 5s. each.
12 varieties of Tea-scented Roses, 9s. per doz.
Yellow Noisette, Yellow and White China, 9s. per doz.
Fine new buff Rose, Eliza Sauvage, 18s. per doz.
New crimson odorata, 12s. per dozen.
Fine new Rose, Le Pectole, pale primrose, 2s. each, or 20s. per dozen.
Queen of the Bourbons, a beautiful Rose, 2s. each, or 20s. per dozen.
All these Roses—or established in small pots—could be shaken out and sent by post.
The new Achimenes picta, 7s. 6d.; hirsuta, 1s. 6d. each.
The dwarf orange Brugmansia, flowering plants, 3s. 6d.
Pentas carnea, 3s. 6d.; Veronica speciosa, 3s. 6d. each.
Gesnera tubiflora, fine new white, 2s. 6d. each.
Inga pulcherrima, 5s. each.
Niphæa oblonga, 2s. each.
Centradenia rosea, 2s. each.

Albion Nursery, Stoke Newington, London.

NEW AND RARE PLANTS.

W. JACKSON AND CO., NURSERYMEN, SEEDSMEN, and FLORISTS, have now the pleasure to offer the following Novelties:—

Cineraria Celestial, No. 1. . . . . 5s. each.
" Fairy, No. 2. . . . . 5s. "

See DR. LINDLEY'S opinion in the *Gardeners' Chronicle*, of April 6, page 216, under the letters, C. L. N. "Seedling No. 1, a bright blue. The flowers of this variety are rather small, but they are very abundant, and bright and beautiful in colour. No. 2, pure white centre, with the termination of the petals of a delicate azure blue. This is also an abundant bloomer with well-formed flowers, lively in appearance, and forms a distinct and desirable variety." Discount to the Trade on the above when six plants of each are ordered.

Boronia ledifolia, 5s.; Chorozema triangularis, 5s.; Epiphyllum, Conway's Giant, 3s. 6d. to 5s.; large E. Russellianum, 2s. 6d.; Gastrolobium spinosum, 5s.; Gompholobium polymorphum luteum, 5s.; Hydrangea Japonica, 2s. 6d.; Mirbelia speciosa, (Loddiges') 5s.; Oxylobium acutum, 5s.; Pimelea spectabilis, 2s. 6d.; Thunbergia chrysops, 7s. 6d.; Veronica speciosa, 2s. 6d. to 7s. 6d. each, large.

W. JACKSON and Co. beg to state that their 60 beautiful Seedling Calceolarias, selected from upwards of 2000, will be sent out early next Spring, a descriptive Catalogue of which will be printed. Railway communication to all parts of the kingdom. A reference from unknown correspondents is respectfully solicited.—Cross-lanes Nursery, Bedale, Yorkshire.

TO THE LOVERS OF PANSIES.

S. WIDNALL, Grantchester Nursery, Cambridge, begs to inform his friends and the public that he has with great care selected his Superior PANSY-SEED, warranted to be all new of the present year, and which he can with confidence recommend. This being a favourable season for sowing, it will be advantageous to those who wish to ornament their gardens with this beautiful flower at a very cheap rate, as packets containing sufficient seed, with careful cultivation, to grow 500 plants and upwards may be had postage free at 2s. 6d. per pckt., or three packets for 6s., upon receiving a post-office order.

VALUABLE NEW PLANTS.—The following are confidently recommended as being infinitely the most beautiful of their respective tribes, and worthy a place in all choice collections:—

Achimenes picta, 7s. 6d. to 15s. each; Gloxinia cartonii, 5s. to 10s. 6d. do.; Cereus carnata, 3s. 6d. do. The Subscribers feel so confident of this Plant giving entire satisfaction, that they are willing to engage to return the money to all who are not pleased with them. They have also now to offer 12 Plants of choicest kinds of Geraniums, including Duke of Cornwall, Sunrise, Fair Maid of Devon, Lord Ebrington, and others equally good, for 21s. the 12, or 2s. 6d. each. 12 most splendid new kinds of Verbenas, 6s. 12 choicest Fuchsias in cultivation, 10s. 6d., sent free by post.—R. WHITE and Co., Poole Nursery, Dorsetshire.

THOS. CRIPPS respectfully offers the following New FUCHSIAS at 24s. per dozen, reserving the selection to himself; or 30s. per dozen if selected by the purchaser, viz.:—Maranck's Princess Sophia, Sidmouthii, Pullen's Adonis, Pendli, Stormontii, Le Chinois, Audot, Queen, Magnet, Pawley's Prince of Wales, Kentish Bride, Duke of Wellington, Bridegroom, Transparens (Oudin's), Akbhar Khan, Sanguinivea, Cylindrica Superba, London Rival, Edwardsii, Victorine, Queen Adelaide (Holmes's). A splendid collection of older kinds at 12s. per dozen.

Also the following select plants, viz.:—Achimenes picta, 10s. 6d.; Habrothamnus fascicularis, 3s. 6d.; Gloxinia rosea alba, 5s.; Thunbergia chrysops, 10s. 6d.; Brugmansia Knightii (new double white), 5s.; Brugmansia floribunda, 5s.; Statice pseudo armeria, 3s. 6d.; Mimulus Moodiana (fine), 2s. 6d.; Mimulus Coleii (the finest scarlet yet out), 3s. 6d.; Hydrangea japonica, 2s. 6d.; Ribes albidum, 3s. 6d., Veronica speciosa, 5s. A remittance or respectable reference accompanied with the order is respectfully requested.

Tunbridge Wells Nursery.

PINE PLANTS.—Persons in want of the above have an opportunity of choosing from a particularly strong and healthy stock, warranted clean, at moderate prices. Apply personally or per post to W. DAVIS, Green-street, Marlboro'-road, Chelsea.

T. AND J. BACKHOUSE, NURSERY & SEEDSMEN, York, beg to offer to the public strong plants of the following new and rare species:—Achimenes picta, 10s. 6d.; Aristolochia gigas, 10s. 6d.; Lisianthus nigrescens, (small) 2s. 6d.

T. and J. B. have also a good stock of Lisianthus Russellianus, Phlox picta, Van Houttei and bicolor, 1s. 6d. each; Achimenes hirsuta, 2s. 6d.; and Pentstemon Murrayana, 2s. 6d.

AURICULA SEED from Stage Flowers, to be had in Packets at 2s 6d., of W. J. NUTTING, Seedsman, 46, Cheapside, London.

NEW PANSY SEED.

WILLIAM CLARK, 25, Bishopsgate-street-within, London, is now sending out Seed just gathered, warranted from the best Flowers and can confidently recommend the same, knowing the kinds collected from; in papers of 2s. 6d. and 5s. each. Also, J. H. Cox, Esq.'s, superb PICOTEE SEED, 5s. per paper. Very fine CALCEOLARIA, from the first flowers, 1s. and 2s. per paper. CINERARIA, from 12 best varieties, 1s. per paper. GERANIUM, fine mixed, 1s. per paper. May be had on receipt of a post-office order.

EARLIEST STRAWBERRY in CULTIVATION.—Strong Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 30s. per 100. As an Early Strawberry, it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the "British Queen," "Deptford Pine," "Prince Albert," and all the leading kinds. To be had of Messrs. WARNER & WARNER, Seedsmen, 28, Cornhill, London.

DUTCH HYACINTHS AND OTHER FLOWER ROOTS.—The undermentioned has received, per Rotterdam Steamer, "Emerald Isle," in FINE CONDITION, an assortment of the above. Early orders for which will secure Good Roots, and upon terms equal to any other Dealer.

T. D. WATKINSON, Seedsman, 6, Market-Place, Manchester.

MR. HOYLE'S NEW SEEDLING GERANIUMS.

WILLIAM MILLER respectfully announces to the Nobility, Gentry, Amateurs, and the Trade, that he has purchased the entire stock of the following superb SEEDLING GERANIUMS raised by G. W. HOYLE, Esq., of Guernsey, viz.:

1844.	each.— £	s.	d.		each.—£	s.	d.
Titus	3	3	0	Claude	1	1	0
Pompey	3	3	0	Sarah Jane	1	1	0
Champion	2	2	0	Amelia	0	10	6
These three for six guineas.				Majestica	0	10	6
1843.				Rosalia	0	10	6
Unique	1	1	0	Flora	0	10	6
Queen of England	1	1	0	General Pollock	0	10	6
				These nine for five guineas.			

The entire set 10 guineas, with a discount of 20 per cent. to the Trade. A remittance must accompany the order from unknown correspondents.

Titus received a seedling prize at Chiswick, June, 1844; Pompey, Champion, and Unique were pronounced by Professor LINDLEY, in the *Gardeners' Chronicle* of June 29, 1844, to be "three flowers of good substance, size, and variety;" and Mr. Gleuny, in *Gardeners' Gazette* June 22, 1844, says, speaking of the Geraniums at the Chiswick Fête—"Mr. Hoyle had by far the best lot there; Pompey was the best of them, and Titus next." Blooms of the others were likewise exhibited at the June Fête, Chiswick, 1844, and attracted very extraordinary attention, and were universally admired. On the whole, the above varieties, for substance, roundness of form, and general excellent qualities, are among the best ever offered to floriculturists. Printed Lists, with full descriptions, can be had on application. To commence sending out plants in October.

W. M. has been supplied by Mr. Hoyle with some choice GERANIUM SEED, which he saved from his own beautiful Seedlings, and the newest and best varieties sent out by other growers. Sealed packets of 100 seeds, 12s.; do. of 50 seeds, 7s. Also, Hybridised Seed, saved from his own extensive collection of Pelargoniums; packets of 100 seeds, 10s.; of 50 seeds, 5s.

Providence Nursery, Ramsgate.

T. DAVIES and Co. beg to offer, at very reduced prices, the following plants, of which they possess a fine healthy stock:—

	£	s.	d.
Auracaria imbricata, 3 to 5 in. high, per 100	4	4	0
Rose Cloth of Gold, per plant . . .	0	5	0
Habrothamnus fasciculatis . . .	0	3	6
Hydrangea japonica	0	2	6
Epacris coccinea	0	5	0
Ilex latifolia, from 15s. to . . .	1	10	0
Berberis tenuifolia, 10s. 6d. to . .	1	1	0
Primula sinensis alba pleno, 3s. 6d. to .	0	7	6
Camellias of almost every kind in cultivation, from 2s. 6d. to	0	5	0

T. D. and Co. can also supply the following SEEDS, which have been collected by them with the greatest possible care:—

GERANIUM.—Positively gathered from their Show-Plants, which have gained all the leading Prizes this year in the neighbourhood of Liverpool, and which cannot fail to produce excellent varieties, if not superior new kinds, 2s. 6d. to 5s. p. packet.

CALCEOLARIA.—From the best varieties out, mixed with their own dark-spotted seedlings, 2s. 6d. to 5s.

CINERARIA.—The most of which has been gathered from the bright blue, mixed with other light varieties, 2s. 6d. to 5s.

PANSY.—Collected from flowers of almost every hue, and of the finest form, 1s. to 2s. 6d.

The larger packets of all, except the Geranium, will produce from 100 to 200 plants.

A liberal discount allowed to the Trade, taking large quantities.—Wavertree Nursery, near Liverpool, Aug 24.

FOR FRAMES, GREENHOUSES, &c.

JOHN HAYES respectfully offers his Composition for rendering Brown Holland, Calico, and Irish Linen Transparent and Waterproof. His own Greenhouse is covered with cloth prepared with this Composition, and answers admirably; the cloth requiring only a coat of boiled oil once a year to render it as lasting as the wood frames; and the plants, which require only half the usual quantity of water, are more vigorous and healthy than under glass.

Specimens of the prepared cloth may be seen at Messrs. BATT and RUTLEY'S, 412, Strand, of whom, or at his Nursery, West-street, Farnham, Surrey, the Composition may be had at 3s. 2d. the quart bottle, sufficient for 100 feet of cloth.

TO AMATEURS.

AN AMATEUR who has a First-rate Collection of CARNATIONS and PICOTEES would be willing to make an exchange with any Gentleman for named TULIPS and RANUNCULUSES.—Direct to A B., Post-office, Tavistock.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND-MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of Seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. In Tin, 1l. 10s. each; or with Copper Box and Tube, 1l. 15s. each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. COTTAM and HALLAN, 2, Winsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers in the United Kingdom; or from the Inventor, by letter, to his address, inclosing a Post-office order for the amount.—RICHARD SMITH, Upper Hall, near Droitwich, Worcestershire.

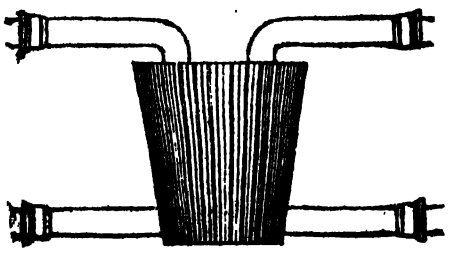
LONDON'S PATENT SPADE.—Sold by GREEN and CONSTABLE, Ironmongers, 26, King William-st., London-bridge. Horticultural Tool Chests, Bright Ladies' Spades, Money's Patent Water Pots, Lord Vernon's Patent Hoes, with a general assortment of Garden Implements.

TANNER'S VITREOUS FLUID and CLOTH, a Substitute for Glass for Horticultural Purposes.—The Vitreous Cloth proves its superiority over Glass, by producing the light most suitable to vegetation, superseding the necessity of any shading, preserving a healthy moisture on the plant, retaining its bloom to a more lengthened period, less expensive, and not requiring so much attention. The above (retaining heat) is preferable to Glass for Hothouses, &c., the temperature of which is maintained with less fuel. It is equally applicable as a covering for Fruit-trees, preserving them from frost, blight, and excessive heat. The Vitreous Cloth, made by machinery, is much superior to any prepared in a different manner. By the use of the Vitreous fluid, the Cloth (after lengthened service) may be renewed.

The Fluid sold in bottles 2s. 6d. and 4s. 6d. The Cloth 2s. 6d. and 3s. per yard. Manufactured by N. W. TANNER, Chemist, Exeter. Agents for Exeter and vicinity, Messrs. LUCOMBE, PINCE, & Co, Exeter Nursery. Liverpool Mr. CUNNINGHAM, Nurseryman, Paradise-street. London: Messrs. BUTLER and MUCKLEY, Herbalists and Seedsmen, Covent garden.

N.B. The Vitreous Cloth if fixed in the manner recommended by the Proprietor) will stand *a much greater pressure* of air than glass.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

BURBIDGE AND HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success; for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.			Patent Door and Frames.	Fire-bars & Dead Plate	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.

12	2 15	30	12 0	7 6	3 0	6	80 to 125 feet.	40 to 65
14	3 10	35	17 5	8 6	4 0	6	150 to 200 feet.	65 to 100
18	5 5	42	25 0	8 6	5 0		300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24	8 15	60	35 0	8 6	7 6		600 to 800 feet	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & C. beg to inform the Trade that at their Manufactory in New Park st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHEWEN, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware road: Rollisson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick, and in the Gardens of the Royal Botanical Society, Regent's-park.

GUANO.—For Sale, in bags of 1 cwt. each; just landed, with a succession of cargoes to arrive.

There being considerable variety in the qualities of Guano imported from different places, and indeed from the same island, each parcel will be chemically analysed with the utmost precision, to show its relative productive power. A copy of such analysis will be given to buyers, and also instructions as to the most approved mode of using the Guano, furnished by the experience of eminent Agriculturists in England and Scotland.

Large parcels will be delivered direct from the Ship, or waterside premises. Smaller quantities may be had at the warehouses, 24 and 25, Billiter-street; or delivered within any reasonable distance, at a trifling additional cost.—Apply to JAMES CLARK, 24, Billiter-street.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS,
ANTONY GIBBS AND SONS, LONDON;
WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Aug. 23, 1844.

GYPSUM, &c.—Pure Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.; also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.
Synopsis of Prices, and mode of use, on application.
MARK FOTHERGILL, 40, Upper Thames street.

GUANO.—The undersigned is ordered to offer the following GUANO of the first analysis and soundest quality, in any quantity, about 40 tons, ex Magnet from Ichaboe, lying at Fenning's Wharf, also a choice cargo of 400 tons hourly expected, to be delivered free at any safe port in the British Isles. CHARLES RIVERS, Sworn Guano Broker,
5, Water lane, Tower-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Aug. 23, 1844:—

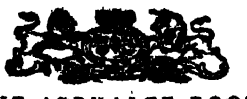
WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

TO FLORISTS AND ADMIRERS OF FLOWERS.
BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

This preparation is peculiarly adapted for the development of Flowers, furnishing them with the material (in a soluble form) out of which they weave their delicate tissues and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing room.—Price 1s. 9d. per quart Bottle, and may be had of WM. JACKSON, late GEO. BUTLER, 93, Cheapside, corner of King-street, and most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas st., Stamford-st., Blackfriars rd.

HATCHER'S BENNENDEN TILE-MACHINE, Manufactured and Sold only by COTTAM and HALLEN, Engineers, Agricultural Implement Makers, &c., 2, Wimsley-street, Oxford-street, London.



This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With the amount of labour, the product of a day of 10 hours is as follows, viz.:—

1 inch diameter of Tile,	11,000
1½ ,, ,, ,,	8,000
1½ inches diameter of Tile,	5,800
2½ ,, ,, ,,	3,300

The Machine is movable down the drying-sheds, so that it requires no extra boys to carry the Tiles, nor are shelves required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Cranbrook, Kent. No charge made for Patent dues or licence. The purchase of the Machine includes free use of it.

ASPHALTE.—BROWN OIL VARNISH, BLACK VARNISH PAINT.—Asphalte in a pure state, without gum, 3s. per cwt., in casks 2 cwt. each, for forming or improving gutters, walks, terraces, court yards, stables, ground floors, roofs, or for applying to damp walls. Brown Oil Varnish for varnishing gates, outhouses, fences, &c., 8d. per gallon—it dries very quickly. Black Varnish Paint for outhouses, fences, &c., 8d. per gallon.—Asphalte Roofing Canvas, very thick, 1s. per square yard.—ROBERT HARRADINE, Maker of Garden Nets, Fishing Nets, Sheep Nets, Rabbit Nets, Tents, Marquees, and improved Tarpaulins, 21, Tenbridge place, corner of Judd street, New-road, London.—N.B. Several thousand Police Capes on Sale.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade.
THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil-Cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch Street, London.

METCALFE'S NEW PATTERN TOOTH-BRUSH and SMYRNA SPONGES.—The Tooth Brush has the important advantage of searching thoroughly into the divisions of the teeth, and cleaning them in the most effectual and extraordinary manner, and is famous for the hairs not coming loose—1s. An improved Clothes Brush, that cleans in a third part of the usual time, and incapable of injuring the finest nap. Penetrating Hair-brushes, with the durable unbleached Russian bristles, which do not soften like common hair. Flesh Brushes, of improved graduated and powerful friction. Velvet Brushes, which act in the most surprising and successful manner. The Genuine Smyrna Sponge, with its preserved valuable properties of absorption, vitality, and durability, by means of direct importations, dispensing with all intermediate parties' profits and destructive bleaching, and securing the luxury of a genuine Smyrna Sponge. Only at METCALFE'S Sole Establishment, 130a, Oxford-street, one door from Holles street.

Caution—Beware of the words "From Metcalfe's," adopted by some houses.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 6, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, city, London.—Mr. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Gallery Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., 50s., and 100s. each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, decks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

TO FLORICULTURISTS, CONNOISSEURS, AND NURSERYMEN.

MR. F. E. STONE will sell by Auction on the premises, No. 22, Park Place West, Liverpool Road, Islington, on Tuesday next, August 27th, at 12 o'clock, a valuable Collection of Cacti, Monstrous, Euphorbia, Aloes, and other Stove and Greenhouse Plants. Also an excellent Tulip Stage 40 feet by 10 feet, and the surplus Household Furniture, a fine-toned 6½-octave Piccolo by Peschey, and other effects. May be viewed on Monday and morning of sale, and Catalogues had on the premises, and of the Auctioneer, 83, St. John street, near Smithfield.

TO MARKET FARMERS AND OTHERS.

WANTED, a MARKET FARM, or Land convertible to that purpose, sufficiently near London to be within reach of the Markets.—Direct to G. M., Post-office, Guildford.

THE FINEST DUTCH HYACINTHS and OTHER BULBS DIRECT FROM HAARLEM.

YOUELL AND CO. beg to inform their Friends and the Public they have just received their first Importation of the above in the finest possible condition, Catalogues of which can be had on application. They are enabled to offer "the finest Double or Single Blue, Red, White, and Yellow Hyacinths at 16s. per dozen."

Very fine ditto . . . . . 12s. per doz.
Fine ditto . . . . . 6s. „

And other Roots at equally moderate prices.

P.S.—Bulbs will be added as compensation for long carriage.

Great Yarmouth Nursery, August 22, 1844.

The Gardeners' Chronicle.

COUNTRY SHOW.

TUESDAY, Aug. 27 Knaresborough Horticultural and Floral.

AT the request of a correspondent, we beg to state that those who are desirous of using SULPHATE OF IRON for the purpose of disinfecting manure may procure it wholesale of Mr. WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street; or Mr. FOTHERGILL, in Thames-street.

NEW flowers or new fruits are not often fit subjects for Leading Articles. But a case has arisen to which it seems desirable to attract particular attention.

Among the countless species of rare plants, for the introduction of which this country is indebted to the Indian Government, there is a little hardy evergreen shrub called "THE SMALL LEAVED OLEASTER," or Elæagnus parvifolia, having the aspect of the Bohemian Olive when out of flower, but being greener, and, like it, exhaling a delicious fragrance when in blossom. The shrub would not attract notice if it were not for its sweetness and being evergreen. The warm summer has brought the plant into fruit, in the Garden of the Horticultural Society; and it is this which leads us to notice it.

Under a south wall it is loaded with clusters of the most beautiful berries, not bigger than a Pea, and totally unlike any fruit as yet found at the dessert. They are oval, and bright red, but all over their skin are scattered innumerable silvery scales, which dim the redness, except where it peeps out between them, and gives the berries a singular mottled appearance. Inside is an angular stone, with a thin shell. The flesh which covers it is of the consistence of a Plum, and of so very pleasant sub-acid a taste, that, if there were more of it, the fruit would certainly be held in as much esteem as Plums.

Now it strikes us that in this instance we have at last the promise of a new class of fruits, if gardeners will set themselves to cultivating it. The plant possesses the important attributes of hardiness, abundant bearing, and good quality; but the fruit is in the usual state of wildings—lean and bony. The latter defect was once the fault of the Peach, the Plum, and the Cherry: we see what cultivation has brought them to; and the success of persevorance without skill in working upon those fruits, seems to justify our hoping as much from the Elæagnus, when subjected to perseverance aided by skill. What chance has brought about in the course of centuries, science may be expected to effect in a few years. In short, we believe that the fruit of the Elæagnus may be brought to the same condition as the Plum, by judicious management.

The course to take is this:—As soon as the plant again shows fruit, every means that experience may suggest should be taken in order to increase the size of a small number of the berries. Those means are excessive thinning, constant watering with liquid manure, and full exposure to the sun. Such means may be expected to increase the size of the berries immediately. The seeds of those berries should be sown in very rich soil; the vigour of the seedlings should be promoted by ample room for the roots, active manure, copious watering, and the brightest sunlight. In two years such appliances will have produced strong seedlings, with an abundance of firm well-formed wood. In the beginning of the third year, the oldest and best wood should be grafted on the common Bohemian Olive (Elæagnus angustifolia), stocks of which should be got ready for the purpose. The succeeding year, the grafts may be expected to bear. When that happens, the same process of manuring, thinning, and sunning should be followed, until the fruit is ripe. Little doubt can exist that the first seedling fruit will indicate a manifest tendency to enlarge; if so, the point is gained—for the moment we can succeed in producing in a plant a disposition to change, we know, from experience, that the change will go a long way, provided we continue to encourage the disposition.

Another way would be, to hybridise this small-leaved Oleaster with the Zinzeyd, or Elæagnus hortensis, whose fruit is as large as an Olive, and eaten in Persia, although it is too insipid for European tastes. By that means an immediate enlargement of the fruit would be certainly obtained; but, perhaps, at the expense of its quality.

Should these remarks attract the attention of any ingenious experimenter, we would suggest, in addition, that some experiments ought at the same time to be made upon grafting the Oleaster, because the operation is not at present practised, and it is uncertain what method may be most successful. And if this point were not determined beforehand, the seedling scions might die, after all the pains of rearing them, and the whole work would require to be commenced over again, or at least an entire season might be lost.

There will probably be some difficulty just now in procuring the Small-leaved Oleaster, but the Fellows of the Horticultural Society will easily obtain it another year. In the meanwhile, if nothing else comes of these suggestions, it is useful to make the tree known, as a capital shrub to be introduced into game preserves, for the sake of its berries. Any quantity of the seed can be procured from the Botanic Garden, Saharunpur.

AMONG the luxuries which seem necessary to the state of a great man's household are all sorts of flowers, fruits, and vegetables, forced into unnatural maturity at unheard-of seasons. The *alienis mensibus æstas* is the measure of patrician gardening; and so completely has the taste for precocious enjoyment fastened on the public mind, that the "forced" things, which opulence only can command, are valued at a great price, while the very same objects, left to Nature for perfection, are too often consigned with indifference to the multitude. Did the expense connected with such unseasonable gardening insure equivalent advantages, it would be a harmless indulgence, and wise mode of eliciting skill and stimulating to exertion. Were the subjects of it, brought to maturity three or four months before their customary period, really improved in quality, or even rendered as good as they naturally are, there would be still greater reasons for its encouragement. But, in the majority of cases, the *pallida poma* of the Romans are only another name for the forced productions of modern England; and many of the objects thus early acquired are inferior, in every important respect, to what they are when suffered to mature at the allotted time. Their great recommendation is, that there must have been an unusual outlay of money and skill in rearing them. Such an outlay may, no doubt, be defended on many grounds, and we are the last to depreciate the consummate skill with which it is often applied. We would only impress upon gardeners that it is not, as is often supposed, the *sole* end of their profession.

The great end of gardening is to improve the qualities assigned to plants by Nature, to the utmost extent of possibility, and it is a secondary object to bring such things into use at any period besides the natural one.

It is therefore a question of some moment, whether those means, which are so efficient in forcing, might not be more usefully employed in ameliorating the same productions at the natural season; and also, whether intrinsic excellence ought not to be sought for more than that fictitious value which attaches to unseasonableness. Let no one fear that wealth would lose its mark if this were so. There can be no difficulty in seeing that money and talent will always keep in advance of limited resources in the hands of the ignorant, and that the distinction which is now attained by forcing would be equally, and we think better, established by superiority of produce. That too is surely a less enviable distinction which depends on having things out of season, than the one which is founded on real and decided excellence of quality.

The majority of vegetables and fruits that are forced are less nutritious, less digestible, less palatable, than natural crops; the standard by which their merit is measured is not so much their good quality as their earliness and external appearance. We, however, regard the highest aim of the grower to be the production of positive rather than comparative superiority; and this can only be effected by assisting Nature at the right time, instead of overstraining her energies by an artificial stimulus. Certainly there are exceptions, but they do not affect the general argument, and we pass them by for the present.

Let it not, however, be supposed that we depreciate forcing, properly so called. We would simply urge that it is not of first-rate importance, and that the greatest share of a gardener's attention should be bestowed on giving his produce the best quality at the season when it naturally appears.

With respect to flowering plants, no one needs telling that their productiveness, their beauty, and the fragrance of their blossoms, are materially lessened by forcing; and yet how many of them are hardly ever grown except for blooming early. The Hyacinth, for instance, is universally used for decorating plant-houses or drawing-rooms, but how few cultivate it as a border flower. To get bad forced Roses in March, is regarded as a matter of more importance than to produce the finest natural Roses in June. To be sure it is very desirable to have Roses, Lilies of the Valley, &c., blossoming in winter. The evil is, that the possession and improvement of plants in such circumstances is often more cared for than when they flourish in all their natural conditions.

It is doubtless a proud feeling for a Gardener that he can chain Nature to his side, and, refractory as she is, that he can bend her to his absolute will. It is a great thing thus to assert his superiority over the menial servants of a household; and we trust that he will ever maintain that empire of intellect which raises him, in the minds of thinking people, above the herd of domestics. But we would submit to him that his power may be exercised and his empire maintained in more ways than one; and that the improvement of the absolute quality of a plant is quite as much worthy of his notice as the forcing its unwilling stores to be given up at all seasons at his imperious command. We none of us like much to act upon compulsion, and we may depend upon it plants agree with us in that respect.

ON "FIXERS" AND "RETARDERS" OF AMMONIA.

I THINK I perceive a little confusion of ideas in the way in which some writers apply the term "fixer" of ammonia to a variety of substances which they recommend for this purpose. I have more than once seen the *Gardeners' Chronicle* quoted as authority on this point; as, for instance, at p. 41 of Mr. Hannam's useful little work on "Waste Manures." Now, surely, it is not judicious to apply the same term "fixer" to the effect produced on carbonate of ammonia by sulphuric acid and certain sulphates, and to that produced by charcoal, bog-mould, &c. By the former class of substances the carbonate of ammonia is decomposed, and the sulphate of ammonia is formed; that is, a volatile salt is replaced by a fixed salt. Here we may say the ammonia is "fixed." But the other class of substances, the charcoal, &c., effect no decomposition of the carbonate of ammonia: they merely "retard" its escape into the atmosphere; they cannot even retain it for an indefinite period. We are, therefore, producing two very different results according as we use a "fixer" or a "retarder." In the former case we shall apply to the soil a result (the sulphate of ammonia) which must undergo a fresh change before it can be serviceable to vegetation; whilst in the latter we apply the carbonate itself ready for action. Without speaking positively, I think we may argue *à priori* that a "fixer" will produce a more permanently valuable effect on manure than a "retarder," if we reason according to the present position of the still advancing inquiry that is making into the theory of vegetation. According to Boussingault it is probable (and Liebig states the same thing), that the sulphate of ammonia must be decomposed, and the carbonate of ammonia restored, before the nitrogen can be fixed in a plant. I find some writers on Agricultural Chemistry very careless in the terms they make use of: they talk of ammonia when they mean carbonate of ammonia, and of lime when they mean carbonate of lime. This conventional negligence may not mislead proficients in chemistry, but we, who are only partially initiated, are sometimes apt to be puzzled by such inaccuracies. Precision in the application of technical terms is the very soul of science. I have penned these remarks in consequence of seeing that Mr. Mechi, in his third letter on Agricultural improvement, speaks of introducing into his tank "a layer of earth or gypsum between each layer of manure," so as to secure the ammonia. I do not know whether it has occurred to him that the action of the two substances here named must be different; the former being what I have called merely a "retarder," whilst the latter may very possibly be truly a "fixer." I have just read Mr. Mechi's letters with very great pleasure. This is indeed something like coming to the point. If Mr. Mechi be correct in his speculation,—and his arguments appear to be generally such as should command attention,—then must our present race of farmers turn over a new leaf, or most assuredly some of them will get pushed from their seats. Mr. Mechi reposes a laudable confidence in what practical men have shown to be advisable, and a wholesome faith in what science has proved to be true. He is now trying, on a very bold scale, to apply the best resources of practice and science to the regeneration (I think we may call it) of a wretched hungry soil, and its conversion into sound fertile land. Let all farmers watch him narrowly, but let them be very cautious of pronouncing him, as it seems by his own account many of them are disposed to do. If his speculation should only prove half as successful as his enterprise and intelligence deserve, the laugh will be sorely against some of our farmers of the old school. Let them rather read Mr. Mechi's letters, and digest them; then, whether this particular speculation of his prove successful or not, they will not fail to profit largely by his reflections, and improve their own notions by his suggestions.—*J. S. Henslow, Hitcham.*

THE ROSE-GARDEN.—No. XVI.

(*Continued from page* 524.)

Annual Pruning.—The annual pruning of the tree Rose takes place in the first week in March. Previous to detailing the manner in which this must be done, it

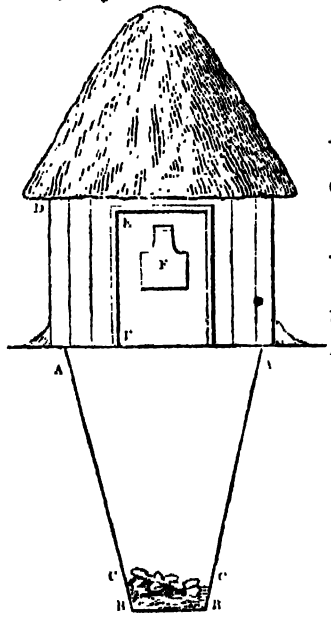
may be well to observe that the growth of a tree is thus:—the rings round the bottom of both stem and branches are the depositaries of dormant buds, which will not be called into action unless the buds above be injured, or unless the sap arise so profusely as to be unable to expend itself by the upper parts, in which case the buds below break out; though, indeed, they will occasionally do so, as the natural act of the tree, in preference to rising higher. This is more observable in the Wild Rose than almost any other plant, and perhaps may, in some degree, explain the reason why budded Roses are shorter lived than those on their own bottom; for any one who has at all observed the growth of wild stocks must have noticed that the original head is seen generally on hedges in much worse plight than the shoots which have been subsequently formed at its base. This tendency of the Dog-Rose to break out below must be checked in two ways: the first, by destroying every sucker and shoot as it starts; and the second, by finding full work for the sap above, and by giving it a free passage. If, then, upon cutting in a tree at pruning time, a couple of buds be left on every shoot of last year's growth, or three at most upon a very strong one (with free growers no rule can well be given), there will be quite enough to occupy the sap, keep the tree within bounds, make it much handsomer, save the sap the expense of maintaining old wood, and give it a free course.

Grafts differ from buds in this respect, viz., that an inserted scion must be considered as a tree which has finished throwing up its suckers, and whose vitality and appearance depends upon the shoots to be produced from buds at the points or sides of the wood already formed. An inserted bud may be considered in the light of a seed sown at the top of a stock, instead of in the ground; it seems to retain the same habits (though limited in extent), and to form its roots, as it were, at the point of insertion, throwing up suckers from thence as it would have done from the ground. Such large shoots, then, as spring at once from an inserted eye, do not come under the same restrictions as those at the points of old wood, which are necessarily more feeble, and the buds upon the bases of which are in a more forward state of preparation for breaking out than the base buds of a vigorous shoot direct from the eye. The latter must be treated according to the position it is intended to occupy; to its strength, and to the state of the wood, and the buds which are upon it. If the buds at the base appear very undefined, and consequently disinclined to break, cutting it in low causes a fresh production of free-growing wood; while, if the same shoot were moderately shortened, the buds at its summits would not only break out freely, and continue the regularity of the tree, but, in the event of excess of sap, recourse would be had to the base buds to expend it. Gardeners, in general, trim such shoots as may be here denominated suckers, or crown shoots, low or high, in proportion to the rest of the tree; but with reference to the health and appearance of the tree, it is only necessary to observe that close cutting is calculated to produce wood, and moderate amputation flower.

If there be more sap than enough, a fresh shoot will likely enough start from the crown of the graft, or the rings upon the first year's shoot, and increase the head of the tree, as well as bring it back with new wood nearer home—a matter always desirable, as tending to keep the head from straggling.

Cutting to the lowest buds always leaves the sap with but a short channel to pass through, strengthens the branch below the buds, and is every way beneficial, if care be taken that a sufficiency be left to occupy the sap.

There are, however, several sorts of Roses, which are, with more or less difficulty, brought to flower when thus treated; and such plants as are found to throw nothing but wood, must frequently be allowed to retain a considerable portion of the last year's produce to insure their flowering: in these cases, a much greater degree of experience is necessary, than when a decided rule can be laid down; the operator must be able to distinguish between flower and wood buds, the former of which are oval, the latter pyramidical: he must learn not only the quantity to be left on each shoot, from the general appearance of the tree, but in a degree also with reference to the shoot itself; thus, pruning the plant altogether in a different manner to that above pointed out, it is obvious that, under such circumstances, it is far more difficult to keep the head near home than when trimming year after year to a stated number of buds; the removal of wood which has straggled away is also more frequent, and the form of the head altogether much more difficult to preserve. Whenever a tree is destined to remain year after year where planted, an equal attention should be paid to the appearance of the future, as well as of the present; but where the current season only is of importance, the plant should be encouraged to produce the greatest possible quantity of flowers; a mode of treatment which has been known to kill fruit-trees entirely. Such plants as throw little or no flower, are in general, from the nature of the thing, more healthy and vigorous than when the contrary is the case, and half standards will therefore be found less productive than whole ones, while the wood is in general finer, the stem more rapidly enlarged, and the head stronger. The larger the shoot, the more likely are the buds upon it to form wood; the bolder the buds, the more likely are they to throw flower; the fifth bud from the base is generally a wood-bud, those above it producing flowers; with a light soil, however, and a hot sun, flower will be produced under any pruning; nor is it by any means uncommon to see a brilliant show of flowers upon old shoots which are annually cut down and layered for the sole purpose of multiplying the number of plants, and of producing wood only.



If the tree be not pruned at all, it will lose its shape entirely in a single year, and become more and more unsightly, each succeeding one. Trimming the shoots has nothing essentially different in the manner of execution to trimming the stock; in trimming to a bud, barely the thickness of a sixpence should be left above the bud, and the excision should form a slant about equal to that caused by dividing a square from angle to angle: if more were left above the bud, it would die down to the bud, and prevent the bark from healing over the wound; in general, the line of the bud is the slant the knife should make in its passage through the shoot.

Cutting out old wood should always take place where it is feasible, the desirable point being to keep near home, as it is called; when, therefore, a tree throws out a fresh and vigorous shoot, close to the base of an old branch which has straggled too far from the graft, the old wood should be cut out in March, close to its base, and the young shoot left to supply its place, and receive its nourishment. This principle, well applied, will always keep the trees in bounds; but as this requires judgment, and cannot well be explained in writing, it may be requisite to take a lesson upon the subject, the first convenient opportunity, from a scientific gardener.

ICE-HOUSES.

Perceiving in a late Number a letter from a correspondent desirous of building a small ice-house at a cheap rate, I beg to inclose a plan of a very cheap one. It would be better to have three or four such small ice-houses than one large one, as the air gets in, and causes the ice in the latter to dissolve before a third of it is consumed. The following plan is proved by experience to be at once cheap and efficacious for its purpose.—*B. D., Greys.*

REFERENCE TO PLAN.

A B A conical hole in the ground.

C B. Stones or rubble, to act as a drain, 18 inches.

A D. Slabs, 4 feet high above the surface.

E. Door.

F. A Trap-door, to answer a similar one on the opposite side, to be opened in a dry air, and carefully closed when the circumambient atmosphere is damp.

THE FLORIST REFORMER.—No. II.

THE POLYANTHUS.

Among Polyanthuses there have not been so many candidates for floral honours as among other florist flowers, consequently there are less synonymes in this class than in any other. The few that have been twice named have been done so apparently by mistake; and those few were raised by Mr. Hufton, of Nottinghamshire, well known for having introduced many good Carnations and Picotees, as well as Polyanthuses. It is said that Mr. Clegg, of this neighbourhood, who bought the stock, named them, and that Mr. Hufton also did the same; they are known principally by the name the latter gave them, in the midland counties.

The Polyanthus has experienced less improvement than any other class of florist flower, and this is principally owing to the great sameness in seedlings to the parent from which they were raised. The following list contains the whole of the Polyanthuses cultivated in this neighbourhood; they are classed according to their merits, and are not distinguished by the colour of the ground—as dark, red, and scarlet.

First Class.

Barrow's Duchess of Sutherland
Buck's George the Fourth
Bullock's Lancer
Clegg's Lord Crewe, *alias* George Canning
Crowshaw's Invincible
Collier's Princess Royal
Cox's Regent
Eckersley's Jolly Dragoon
Gibbon's Sovereign
General Bolivar
Fletcher's Defiance
Hilton's President
Hufton's Earl Grey, *alias* Clegg's Lord John Russell
Hufton's Lord Rancliffe, *alias* Clegg's Prince of Orange and Clegg's Golden Hero
Hufton's Lord Lincoln
Maude's Beauty of England
Nicholson's Bang Europe
Ollier's Beauty of Over
Pearson's Alexander
Saunders's Cheshire Favourite
Wood's Espartero
Goud's Independent.

Second Class.

Beauty of Coven
Buckley's Squire Starkie
Burnard's Formosa
Dew's Britannia
Faulkner's Black Prince
Fillingham's Tantarara
Queen's Earl Fitzwilliam
Hepworth's Elizabeth
Jolly Sailor
Nicholson's Ranger
" Nonsuch
" King
Sir Sidney Smith
Head's Telegraph
Turner's Emperor Buonaparte
" Princess
Timm's Defiance and
Yorkshire Regent

—*John Slater, Cheetham Hill, Manchester.*

Home Correspondence.

Ice-Houses.—Ice being water in a solid form, acquires its solidity by the process of losing its heat. It is a law of matter, that when a mass of ice shall, by absorption, imbibe a certain amount of heat, equivalent to that which it has lost during the process of congealing, it assumes its natural or fluid state. If two bodies of equal solidity are placed near each other, the one heated, the other of the temperature of the surrounding atmosphere, it will be found that, after a short time, the heated body will, by the law of radiation, lose its heat, and the cold body, by absorption, will imbibe a portion of that heat until both indicate the same temperature. The more compact a body is, the slower it is in acquiring heat, and it is equally slow in parting with it. Now I consider the ice-house and the surrounding atmosphere as two bodies, the one (the atmosphere) being heated, and the other cold; consequently the colder body, viz. the ice, will absorb the heat radiated by the surrounding medium, the result of which is, that the ice resumes its fluid state. From these remarks it would appear that one great object in the preservation of ice is to exclude the air by every possible means. Many do take this precaution; but in contradiction to this, I beg to mention the practice of a gentleman who frequently, during the warm days of spring and early summer, (for he never has any ice afterwards,) orders the ice-house doors to be thrown open for a few hours, to dry, as he expresses it, the ice and walls of the building. This he denominates the American mode; and, for those who wish to hasten the departure of their ice, a most efficient mode it is. With respect to the situation of the ice-house, if the place is dry and well screened from the sun, little importance is to be attached: the great secret lies in the body of ice being compact, in order that it may resist, as much as possible, the absorption of heat; and, for becoming as solid as possible, there is no substance so good as snow, which possess all the qualities of ice. I am sure that if snow was well beaten and trodden until the ice-house was quite full, beginning the treading at the bottom, and gradually proceeding, making quite firm each thin layer, to the top, the body of snow would acquire such compactness as would resist the heat of our summers. For instance, how often do we see the snow-balls which the schoolboy makes, resist the action of the open air and sun for days, while a heap of ice of equal size would disappear in half the time, from the fact that it is less compact, and therefore absorbs heat more readily? If ice could, by any means, be reduced to powder similar to snow, the result would be far better than under the present method, although the water, which is necessarily mingled with it, would, in some measure, spoil its keeping. In Italy, where ice is looked upon not only as a luxury, but as a necessary of life, the inhabitants of the mountains, in order to meet the demands of the valleys, collect the snow, and, packing it into the fissures of the rocks on the shady side of the mountains, find no difficulty in keeping a supply when the heat of summer has arrived. From this source is derived all the snow which cools the drinks of the thirsty Neapolitan, and which enables him to wash down his favourite dish of maccaroni, or cool his palate beneath a cloudless sky.—*Walter Wakefield.*

Bees.—The history of the bee has been written with so much truth by Huber, that little is left for inquiry. I know but of one error, which is, I presume, by the translator. The extraordinary fecundity of a queen is stated to be 200 eggs a day. A queen which deposited no more eggs than that, could never produce a swarm, on account of the daily loss of bees which go out to the fields. I have had queens which laid 1000 eggs daily for three months in succession. This summer, in a glass hive containing one comb four feet square, the queen deposited 800 eggs a day, or 16,000 in 20 days, 2000 of which were males. My glass hive is two feet square; the glasses are one inch and a half apart, which compels the bees to build but one comb. The object of this communication is to inquire if any correspondent can solve the following queries:—As the queen knows when she is to lay a drone or male egg, in what way is that knowledge acquired? What difference is there in the size of male and common eggs? Does one ovary contain male eggs only, or are they to be found in every ovary?—*A Lover of Truth.*

Guano.—A neighbour of mine has found among his guano a perfect egg. Is this usual? The egg is about the size of a duck's: it is discoloured by the guano, but does not appear to have been speckled or mottled. The shell is very firm, and the interior is so dried as to rattle on shaking the egg.—*Frederick H. Sankey.*

Liquid Manure.—The dryness of the season has been very unfavourable to the growth of summer Cauliflowers. I sowed some seed about the end of February, on a slight hot-bed, protected only by mats; after being planted out, they suffered severely, both from the weather and from grubs; and it was only by means of frequent watering that I saved a fair quantity. Having good faith in liquid manure, I gave each of them one good dose of it, and notwithstanding the dry weather, I have had a much better crop than I expected. I cut a head last week which weighed 3lbs., and another since—dressed in the usual manner for cooking—which weighed 5½ lbs. It measured 10 inches in diameter, and 30 inches in circumference; this is a proof of the value of liquid manure for this much esteemed vegetable. The plants were not over-grown, but were close and compact, and were not attacked by grubs, which were very troublesome during spring and summer. I am not aware of any effectual mode of destroying them, and would be glad to receive a hint on the subject. I contemplate

dressing a piece of ground with lime and soot, having it well dug, and allowing it to lie exposed to the weather all winter, in the hope that this may eradicate the evil. I have lately applied a good dose of liquid manure to all my winter Greens, and I can already perceive a most beneficial result; they have made rapid growth during these last few days.—*Henry A. Wood, Statfold Hall.*

Growth of Trees.—As you say, in reply to my question about the growth of forest-trees, that you are not aware of any exact observations on the subject, and as your correspondent of last week only repeats an old story of an observation very imperfectly taken, you will, I hope, allow me to state the result of my experience, which causes me to doubt the generally received opinion, that wood lengthens after being formed. The Fir-tribe offer the most convenient subjects for inquiry, as the growth of each year is in them clearly defined, as far as the lower branches are permitted to remain on them; and I find that Spruce-trees in a sheltered situation, in the fifth year of their growth, form top-shoots measuring as much as 2 feet 4 inches, and in the seventh year, as much as 3 feet; and in the same kind of tree, equally sheltered and in the same soil, I find that on trees aged 18 years the shoots, which were formed in the fifth and seventh years of their growth, do not exceed those measurements. I have also found that an Oak-tree of about 30 years' growth which I measured in two places, which I marked, for the purpose of ascertaining its increase in circumference, did not lengthen between the marks, although it increased in circumference about 2 inches in one year.—*A Subscriber, Ireland.*

Miltonia Spectabilis.—At the last Glasgow Horticultural Society's Exhibition there was, among other well-grown specimens of plants sent by Mr. Turnbull, gardener at Bothwell Castle, a very fine one of this rare plant, about 3 feet in diameter, with some 35 expanded blossoms, and a good many more to open; the leaves were of a very dark green, which is also quite unusual with the plant.—*A Subscriber.* [We have seen nothing like this in the south.]

The Polmaise Heating.—I believe there are upwards of ten or a dozen different systems of heating hothouses described in the *Chronicle*, but perhaps none of them possess the essential properties to such a degree as the Polmaise system, namely, simplicity and efficacy. I have seen the new vinery that has been erected at Polmaise, by William Murray, Esq., and it only requires to be seen at present to be admired; the luxuriance of the Vines, the size and number of the bunches and berries, all testify that the system upon which the house is worked is one that agrees well with the growth of the Vine. If those who have not seen it would only imagine luxuriant shoots, with leaves approaching in size to the foliage of the Tussilago Petasites, with clusters of the black Hamburgh Grape more than a foot long, with enormous shoulders supported with small cords, they might have some idea of the plants and fruit at present growing in the vinery at Polmaise, heated by means of hot air issuing from a chamber at the back of the vinery. There is another thing attending the Polmaise heating, which, perhaps, may be worth noticing, namely, the crest-fallen appearance of some who considered themselves among the best Grape-growers in Scotland; they have watched the progress of the Vines from time to time, and at present they consider themselves beaten. Some of them may not be fond of innovations, but in order to raise their dejected spirits, and maintain their character as successful cultivators of the Vine, some change must be made in their present system. I was informed by Mr. Carmichael, the gardener, that the difference of temperature between the front of the house and that part where the hot air enters is only about 5 degrees; he also showed me a graft which he put upon one of the Vines. This season, it has made a shoot corresponding in strength with the other Vines in the house; it has also a bunch of Grapes upon it: the variety is the Muscat of Alexandria. It is thought by some Grape-growers that this variety should have a small vinery for itself, as it requires a higher temperature; but a short time will prove how it agrees with its new situation. At present, the Vines in the house grow as freely as common Cabbages in a well-manured garden, or Willows by wet ditches.—*Peter Mackenzie.*

The Grey Parrot.—"A Constant Reader" wishes to be informed if any remedy can be applied to prevent a favourite bird picking off its feathers. The usual food has been bread and milk, chicken bones, &c., but notwithstanding every attention to diet, the unsightly bird continues to devour every wing and tail feather as soon as they appear.—*N. S. H.*

Destroying Wasps.—The mode of destroying wasps described at p. 541 is a very old affair, and by no means so simple and effectual as the one with turpentine, discovered by Professor Henslow, and detailed in the *Gardeners' Chronicle*, p. 637, 1842. Even on this latter method, however, a great improvement has been made by putting the turpentine in a bottle, instead of a cup, and inserting the neck of the bottle in the hole leading to the nest, and surrounding it with some earth, in the way recommended by a correspondent, "B. C. K.," at p. 556, vol. 1843. Very little turpentine is required—merely as much as will wet the sides of the bottle. If applied in the dusk of the evening, every wasp will be dead by the following morning. In no instance have I known it to fail of the desired effect, excepting in cases where the nest was deeper in the ground or at a greater distance from the mouth of the hole than I had anticipated. A partial failure may sometimes occur where there happens to be two entrances to the nest instead of one, but a second application the following evening is sure to prove effectual.—*M. E. H.*

Abies Douglasii.—The following account of the loss of a very fine Abies Douglasii may prove interesting to some of your readers. In the year 1830 I received from the Horticultural Society's Garden, at Chiswick, two plants of Pinus ponderosa, one of P. cembra, and one of A. Douglasii. They were all planted in a shrubbery here together with a young Deodar plant, the soil being a fine light loam, formerly a garden. All throve well for about five or six years, when the two Ponderosas were attacked by an insect which fed on the pith of the young shoots, and every year destroyed them. The plants, consequently, got stunted and deformed; one was taken up, and the other, though still alive and making efforts to recover, presents a wretched spectacle of disease. The others throve apace; the Cembra is a noble-looking tree, a picture of health and beauty; but the Douglasii and the Deodar became the admiration of all who saw them, and confessedly, so far as I was assured by many well-informed gardeners and nurserymen, the finest specimens in Scotland. The Douglasii had attained the height of more than 30 feet, being a growth of more than 2 feet (about 2¼ feet) per annum. During the summer before last (1843), we remarked that two of the lower branches dried up and withered; but as the tree still looked vigorous, we hoped it was owing to some accidental cause. In the winter, however, I remarked a less healthy hue stealing over other branches; and in spring, while the other trees were beginning to make their shoots, the unfortunate Douglasii was observed gradually to change colour, like a branch separated from the stem: no swelling of the buds took place, and by the end of May, when I returned from an absence of some months, it had become red as if scorched with fire—the tree was dead. A friend in the neighbourhood, who has very extensive plantations, and who has studied the matter much, having called one day and seeing what had occurred, suggested that the cause would probably be found to be in the roots having struck through the congenial soil into some unfriendly stratum below; and that, as all of the Silver Fir species love a moist soil, this had in all likelihood penetrated to the dry gravel which forms much of our subsoil. His forester having come some days after, examined the spot with my gardener; and, on digging beside the tree, found that the roots had struck into a dead sand, where they had been literally starved. The unusually dry weather of this spring had accelerated the catastrophe. The Cembra continues as healthy and vigorous as ever; and the Deodar, though not more than 11 feet high, spreads its thick pensile branches over a circumference of 10 yards, resembling a fountain of green waters in the regularity of its weeping boughs.—*James B. Fraser, Moniack, Inverness.*

Local Horticultural Societies.—Mrs. Thomas Lewin, principal secretary and treasurer of the Eltham Horticultural Society, presents compliments to the Editor of the *Gardeners' Chronicle*, and begs to contradict the statement lately given in it of the falling to the ground of the above Association. Being assured it cannot be his wish to discountenance the smallest exertions in such a cause, she begs to tender her assurance, that though its object is little more than parochial improvement, and had not been supposed worthy of notice in such a register as the *Chronicle*, yet that its Editor may record it as doing successfully, and affording an example easy of imitation to all parishes where a few persons will take the management of it.—*Barn House, Eltham.* [We hope our correspondents will be in future more cautious in their reports of dead Societies. We rejoice to find that the Eltham is flourishing, and wish it all the success its managers can desire.]

Flower Garden at Tandridge Court.—I imagine that if my neighbour, "W. H. M." had resided in the neighbourhood at the time the Flower Gardens were made here, which is nearly ten years ago, he would have found that the first operation was draining. If he had referred to my former statement, he would have found the pond mentioned in it. To our great disappointment, we found only one spring, and the water from it is conveyed through the garden in an iron pipe. "W. H. M." might have stated that, in order to add to the number of beds, the present design of the Flower Garden is the third that has been made on the same spot. He might also have stated that some of the beds are on a sandy bank, and look equally well with those in the horse-pond.—*J. Clark, Tandridge Court, Surrey.*

Pine-Apples.—In February last I had about 100 Pine-suckers potted into six-inch pots, and plunged over the rims of the pots, in a bed composed of two-thirds leaves, and one-third fresh tan, 20 inches deep, and heated by means of hot-water tanks below. In May the plants having filled the small pots with roots, were shifted into pots 10 inches wide and 9 inches deep, the sides being perforated. These were plunged in the same pit, so that the rims of the pots were 2 inches below the surface of the bed. The plants grew very well, making stiff short leaves of the finest healthy hue. On the 12th of this month I took them out of the pit again, and found that not only the pots were filled with roots, but that they had extended through the holes at the sides, and over the rims of the pots, in many cases as much as 20 inches. The plants were not watered during the whole season, but merely syringed overhead on the afternoons of fine days. The bed was always in a medium state of dryness, and the soil in the pots was the same. Perhaps those who are now engaged in discussing the relative fitness of leaves and tan for Pines to root in, will be able to draw some conclusion from these facts that may help to set the matter at rest. I will only add, that nothing could be more satisfactory to myself than the present state of the plants, many of which I hope to have in fruit in February next.—*G. Fleming, Trentham.*

Valerian Root.—No doubt many unverified traditions have been perpetuated, and some from a remote antiquity, without sufficient inquiry. How is this, as to the continually re-asserted predilection of cats for Valerian? Thinking it might have remedial effects, in case of indisposition, I tried it. I found the cat would drink an infusion of druggist's Valerian, with plenty of milk, but not at all without. I found no disposition to touch or smell the drug, or the fingers which had handled it. The same indifference was manifested for the leaves, stem, and blossom of fresh Valerian. I find no difference between cat and kitten in this respect, and can discover no appearance of truth in the story. Can you either affirm or deny it? The same questions apply to the Mint called Nepeta Cataria. But I cannot try it, as I do not know the plant, or where to find it.—*A. H.* [If your Valerian roots are fresh, and given to male cats, you will soon find that the influence of it is perceptible enough.]

Transmutation of Corn.—In the *Gardeners' Chronicle* of the 17th inst., I observe an article in which you give an account of an experiment tried by Lord Bristol, suggested by the old German notion that one species of grain, if cut over in an early stage of its growth, will in the following year produce grain of another description. Having heard of this hypothesis several years ago, I determined to test it. Accordingly I sowed a small patch in the kitchen garden with Oats, and cut them over several times before the flowering stems appeared. The following spring many of the plants were dead, but the leaves of those which remained had very much the appearance of Barley. I showed this to Mr. Smith, of Deanston, and several other eminent agriculturists, who thought that the plants were of the Barley species; and I had not previously informed them why I wished to have their opinion. They grew luxuriantly, and in the course of a few weeks I felt the ear in the sheath, which, when it opened, showed magnificent seeds of Timothy Grass. Whether this was a transmutation, or whether the Oat plants had died, and dormant seeds of Timothy Grass had taken their place, I know not. I determined to try the experiment again, and did so with Oats, Barley, and Wheat. I gave these the same treatment as in the former case; and the second year, although many of the plants had died, those which survived showed ears of Oats, Barley, and Wheat, just as they had been sown. I am determined again to test this theory, and, by way of greater security, I mean to sow the grains in flower-pots—two seeds in each, having the mould well examined to prevent, if possible, the presence of any other seeds. Although rather late for this season, still I shall try it this year, as well as next at an earlier period.—*J. S. R.*

Foreign Correspondence.

Extract of a Letter from one of the Secretaries to the Wellington (New Zealand) Horticultural Society; dated Wellington, 19th Feb., 1844.—His Excellency has granted to our Society 10 acres of land in a very convenient situation, for the purposes of a garden, and we only want increased funds to avail ourselves to the utmost of this liberal provision. I was led to recommend the packing of fruit and other trees in zinc cases through an inadvertence it is needless to explain; and I regret this the more, as it may be productive of injurious consequences. The trees—Apple and Pear—to which I alluded in my former letter, and which, after being nine months out of the ground (the vessel not sailing until five months after the time stipulated in the advertisement), are now flourishing in my garden, some of them having borne fruit this season, were packed in a deal case, in Moss only, and without straw. At Valparaiso I witnessed another successful instance of this way of packing. A Frenchman arrived there, after a voyage of nearly four months, with several cases of flowering shrubs and trees from France, in the very best order. They had each a small ball of earth to the roots, which were afterwards wrapped in Moss, and the plants were packed in the same material to prevent their being disturbed. I am anxious to correct any error, because a case of plants was sent to us by the London Horticultural Society, packed air-tight, and they all perished. In the warm latitudes these air-tight cases prevent evaporation, and this causes fermentation, especially if straw be used, as in the instance of a case I received, with the other alluded to above, containing Peach, Plum, Gooseberry, and Currant-trees, all of which died. I hope a better fate is reserved for the Vines you are good enough to promise us, and which I expect with great impatience. They shall receive every care, and I have provided for them an excellent situation. I feel greatly obliged by your promise of the Poppy and other seeds; if I may venture a suggestion, you cannot forward them in a better way than by post, inclosed in brown paper, as a letter, or as you sent the Trifolium, every seed of which grew, and it has since been widely disseminated through this and the neighbouring settlements. You would also greatly oblige me by sending in this way a few Cucumber and Melon seeds; Cucumber seeds I have not yet been able to save in the colony. I am making another effort this year. From the inquiries I have made I find neither Box for borders nor the Lily of the Valley are to be obtained in Sydney or Van Diemen's Land; the common Primrose and double and single Violets, we have. I must confess a great partiality for the established favourites of the gardens of our fatherland; they have a double charm, from early associations.

I am anxious to make a collection of Roses—in my opinion the most magnificent flower in a garden; I have nine varieties, and have written to England for 20 others. It requires some philosophy and patience to tax the imagination while we indulge in the pleasures of anticipation, until at length we have those of fruition; but I believe the collection of useful and ornamental trees or plants in the colony is more complete than could be reasonably expected in so short a time. While on this subject, I may mention a curious fact I learned at Tahiti. Some 30 years since a well-meaning person thought to confer a benefit on the island by introducing the Guava. It has since spread most rapidly, and is now the pest of this place, as it is necessary to eradicate it whenever cultivation is attempted, it is, in truth, the only clearing required. I will take care to make a collection of dried specimens for you, as you wish, and forward them by some convenient opportunity. I refer you to those *Gazettes* containing an account of the establishment of an Agricultural Association, and two articles written by myself advocating its uses, to show that your suggestions have been attended to, where any hope of success presented itself. You will be glad to learn that the harvest this year has been very good, they are now busy cutting, the weather is very fine, and there is every prospect of an abundant return.—*Robert Stokes.*

COUNTRY SHOWS.

Cambridge Florists' Society, July 25.—At this Exhibition the following Prizes were awarded CARNATIONS—Mr Twitchett, P P, Hendly's Empress of Purples *Scarlet, Bizarres* Mr R Headly, Rainsforth's Gameboy, Mr Twitchett Twitchett's Don John; Mr Ready, do *Crimson Bizarres* Mr Twitchett, Kly's Lord Milton Mr Marshall, Munsley's Robert Burns Mr R. Devon and Exeter Botanical and Horticultural Society.—This was the 46th Exhibition; the weather was most auspicious, and the company numerous. From the garden of Miss Wells were a fine Cattleya Harrisoniæ, Stanhopea oculata and insignis; Eyanthe Deppei and Skinneri, &c. Of *Stove or Hothouse Plants*, Ixora coccinea, a good I. crucata, Cyrtoceras reflexa, Rondeletia speciosa, Achimenes hirsuta and multiflora, &c. Of *Green House Plants* Phœnocoma prolifera and Cruasula cotcinea, Baschnaultia formosa, Boronia pinnata, Pimelea Hendersoni, &c. The *Heaths* were remarkably fine, containing good specimens of ampullacea, reflexa, alba, tricolor, inflata and jasminiflora, &c. *Pelargoniums* comprised Beck's Leonora, Admiral, Meteor, Lynch's Sunrise, and Duke of Cornwall, &c. A fine plant of Lilium lancifolium, and some cut Flowers were also from the same collection. From the garden of J. W. Buller, Esq., were Cattleya Harrisoniæ, Oncidium flexuosum, O. Papilio, Aeropera Leddigesii. *Stove Plants* Pavetta caffra, a noble plant 9 feet high, and covered with 200 bunches of white blossoms; a fine Clerodendron squamatum, and C. paniculatum, Ixora coccinea, Rondeletia speciosa. *Greenhouse Plants* A fine plant of Boronia ciliata, Aphelexis humilis, a good Baschnaultia formosa, Michelia dilatata, Boronia crenulata, Tecoma jasminoides, and a fine specimen of Fuchsia exoniensis. From Mr Buller's were also a collection of Verbenas, Cinerarias, and Balsams. Mr. R. Webber had a stand of *Carnations* and *Picotees*, among them we noticed Hogg's Champion, Queen of Sheba, Wilson's William IV, Harry Giddings, Lady Paget, Countess of Surrey, Heath's Superb, Duchess of Kent, Clark's Wellington, Burtle's Lady Talbot. Of PEARS there was a fine display, for which the following prizes were awarded.—*Pine Apple* 1, Enville, 7½ lbs., E Lousada, Esq; 2, Queen, 6 lbs., Mrs Wells Dish of white *Grapes* Muscat of Alexandria, E Lousada, Esq Best flavoured *Melon* Blackhall Green-flesh, 3 Kingdon, Esq *Apricots* Moor Park, J. W. Buller, Esq. *Nectarines* 1, Red Roman, Sir J Kennaway, Bart., 2, Kingdon, H. Porter, Esq *Plums*: Orleans, H. Porter, Esq. *Cherries* Bigarreau, Sir J Kennaway, Bart; May Duke, F. Cross, Esq. *Red Gooseberries* Roaring Lion, H. Porter, Esq *White ditto*; Batt's Favourite or Old Dutch H Porter Esq., *Yellow ditto* Royal Sovereign, H Porter, Esq; *Green ditto* Ocean, J W. Buller, Esq *Red Raspberries* Antwerp, J W Buller, Esq. *Dessert Apples*; Jennating, T W Gray, Esq *Dessert Pears*: Citron des Carmes, H. Porter, Esq *Strawberries* Elton, H. Kingdon, Esq.—*Exeter Flying Post.*

Forres and Nairn Horticultural Society.—This was the summer Exhibition. The show of flowers was equal, if not superior, to that of any former meeting. Fruit and Vegetables were rather scarce, owing to the late unfavourable season. The Prizes awarded are as follow.—*Calceolarias* 1st, Mr Mackenzie, gr. to J Dunbar, Esq., for Duchess of Buccleuch, Lady Constable, Lady Peel, Armosa, Ellen, Grandiflora, Lord of Richmond Hill, and Bain's Queen Victoria. *Pelargoniums* Mr. Hopkirk, gr. to Major C. Bruce, M P., for Prince Queen's Alicia, Gem of the West, Garth's Perfection, Carnoustie, Miss Rupert, Britannia, Alexandrina, Victory, Fancy Band, Princess Royal. *Stove Plants* Mr Hall, gr. to Sir John Dunbar, Bart., for Hoya carnosa, Thunbergia alata and Gloxinia speciosa. *Greenhouse Plants* Mr. Hall, for Acacia Riceana, Thunbergia alata, Pimelea spectabilis, Epacris grandiflora, and Fuchsia globosa; 2, Mr Mackenzie, for Acacia [illegible]

Mr to N. M'Leod, Esq., for Hindostan; Dingillah. Epiphyllum Jenkinsonii, Echinocactus, Cereus speciosissimus, and Leschenaultia formosa. *Specimen Fuchsia*; Mr. Hall, for Chandleri (Variegata Mr. Hopkirk, for Splendens, Royal Sheen, King, and North Star. *Petunias*: Mr. Mackenzie, gr., May House, for Superba, Vesuvius, Squib's Seedling, Magnificissima, Mrs Weymss, and a seedling. *Stove Plant* 1, Mr Hall, for Manettia bicolor; 2, Mr. M'Kenzie, for three varieties *Pelargoniums*. Mr Mackenzie, for Jewess, Victory, and Alexandrina. The following articles were sent for exhibition from Delvey.—The carious Pitcher Plant (Nepenthes distillatoria), the Butterfly Plant (Oncidium Papilio), Erica ventricosa superba, v praguana, tenella, ignea, celsii hybrida, perspicua, &c; Polygala speciosa, Leschenaultia formosa, and Pimelea decussata; also a Ward's case containing Heaths, Oncidium flexuosum, &c. From Altyre—Gloxinia maculata, rubra, Youngii, and several seedlings. From Mr. J. Gillan, Epiphyllum Jenkinsonii, Ackermanni and speciosum, Cereus speciosissimus and flagelliformis. from Spa Park—Erica ventricosa, and ovata, Leschenaultia biloba, and Statice arborea. From Holm—Gloxinia candida, double Yellow Rose, &c. From Springfield Cottage—Victoria Rhubarb.—*Forres Gazette.*

North Riding Horticultural and Floricultural Society, July 30.—This was the second meeting for the present season. The plants in pots cut flowers fruits, and vegetables were numerous and in great perfection. The Prizes were awarded as follows.—*Stove Plant in Pot* 1, Miss Parkin, for Achimenes grandiflora, 2 Mr Pinkney gr to I S Walker, Esq for Hedychium coronarium *Greenhouse Plant in Pot* 1 Mr May for Lilium lancifolium punctatum 2 Mr Jackson for Erica ventricosa superba *Fuchsias* 1, Mr May for Staniwelliana, 2 Mr Jackson for Formosa elegans Among Fruit, Mr Graham obtained a first Prize for Frontignan Grapes

The Norfolk and Norwich Horticultural Society.—This was an excellent show for the season. The collections of Picotees were larger than on former years. A seedling exhibited by Mr H Cooke, was said to be of first rate quality. The petal is of the Rose form, of fine substance; the crown is well up and the habit excellent. The Fuchsias were well grown and presented a rich appearance. A Yucca gloriosa in bloom was exhibited by Mr Short, gr to Mr J Stracey. Mr Short, gr to H N Burroughes, Esq., showed a seedling Dahlia of good form and substance which if it retains its habit will be a valuable flower. Its colour is a deep velvety dark maroon. Melons, though numerous, were scarcely so fine as on former occasions. Strawberries were fine in size, but they were not well flavoured. From the gardens, Bracondale, were Erica Hartnelli Irbyana, viridiflora ampullacea, Epacris Tasmanii, Jasminum nitidum, refulgens, gemmiflora, Fuchsia Britannia, Paragon, Kentish Hero, Mrs Busta, Princeps, Alata, Eclipse, Nobilissima, Majestica, Duke of Wellington, Brockmanni, Lindleyana, Maria Champion, Exoniensis, Campanula fragilis, Achimenes longiflora, grandiflora, and rosea, Rivina humilis, Crowea saligna, Lycopodium stoloniferum and denticulatum, Polypodium aureum, Nerium splendens, Sollya salicifolia, Lasianthus Russellianus, Acrostichum alcicorne. The following prizes were awarded—*Dahlias (white ground)* R Fellowes, Esq., for Kirtland's Queen Victoria, Miss Bacon, Miss Jane, Miss Irby, Rose Harry, La Polka, Princess Royal, Teazer, Purpurea elegans, Rod River, Rebecca, Joan of Arc, Sir W Middleton, Harlequin, Maid of Orleans, Mrs Bevan, The Queen, Nottingham Hero, Burroughes's Seedling, Parmegiano, Fair Flora, Grace Darling and Nulli Secundus. *Fuchsias* Mr Short, gr to H N Burroughes, Esq for Formosa elegans, Stylosa minima, St Clare, Globosa major, Conspicua, Rubella, Standishii, Blanda, Insignis, Magnifica, Dalstonii, Venus Victrix, Chandleri, Grandis, Youngii, Invincible, Carnea, and Racemifera, Maurandya Barclayana alba, C Middleton Esq Ipomœa Learii, Mr Short *Pine Apples* Queen Mr Stewart, gr to W Bagge, Esq, M P *Grapes* Black Hamburgh, Mr Gale, gr to H N Burroughes, Esq, Grizzly Frontignan, extra prize, C K Thompson Esq.—*Norwich Mercury Aug 3*

Reviews.

Gramina Britannica, or Representations of the British Grasses, with Remarks and occasional Descriptions. By J. L. Knapp Esq. 2d Edition, 4to. Longmans.

THE late President of the Linnæan Society called the first edition of this book "an elaborate work," and not without reason. Its fault has always been its rarity—an evil now remedied by the issue of a second edition.

It is a volume of 119 coloured 4to plates of Grasses, drawn with great care, and offering such excellent likenesses that a person of no botanical skill cannot fail to recognise the species by their assistance. And this gives Mr. Knapp's book great value, for the larger part of the persons interested in the art of distinguishing Grasses are country gentlemen and farmers, who know nothing of Botany, and cannot use the technical descriptions or analytical figures of Botanists. To that great class such a book is invaluable. It ought, in fact, to form a part of the library of every one interested in rural affairs who can afford to buy it, for there are few plants so difficult to distinguish as Grasses, not any more so, and none which it is more important to know correctly, because of their various uses and qualities. With Mr. Knapp's book before him no one can have the least difficulty in making himself master of the subject.

We must also add, that the plates are tastefully drawn and carefully coloured, and the printing a beautiful specimen of typography, so that the work, independently of its practical value, forms a handsome drawing-room volume. Indeed, we know of no book of its kind so exactly what would be wished for by a lady who is turning her attention to the study of this interesting branch of Botany.

Orchideæ in the Collection of Conrad Loddiges & Sons. 12mo. 1844.

A NEW edition of this remarkable Catalogue has just appeared. In addition to its other merits, it now includes references to the books in which species are figured, which makes it extremely useful as a book of reference. The enormous extent of Messrs. Loddiges' collection may be judged of when we mention that the numbers of Orchidaceæ cultivated by them now, extend to 1916. The highest number in the last Catalogue was 1654.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

Myrsiphyllum asparagoides. Smilaceæ. Stove Climber. Native of Madagascar. Introduced by Messrs. Veitch, of Exeter, from Mauritius. Flowers white, in small axillary umbels. Leaves linear, in fascicles of 3 to 6. Stem climbing, smooth, and armed with numerous prickles. Flowers in July and August.

Cinchona micrantha. Cinchonaceæ. Greenhouse Shrub. Native of Peru. Introduced by Messrs. Veitch, of Exeter, from Mauritius. Flowers white, in terminal panicles. Leaves ovate, acuminate, glabrous, and shining. Flowers in July and August.

Pentandra Hookeryana.—The generic distinction is taken from this species, which has the stamens alternately longer and shorter. Cinchonaceæ. Stove Shrub. Native of Ceylon. Introduced by Messrs. Veitch, of Exeter, from Mauritius. Flowers white, in terminal panicles. Leaves ovate, acuminate, glabrous, and shining. Flowers in July and August.

Viola odorata. Violaceæ. Hardy Perennial. Native of Britain

[illegible] hardy and permanent shrub. These judicious kinds of exposing plants will do much to place a proper value on those from the high regions of tropical mountains, and will read a lesson to many who select warm corner and sheltered sites for plants otherwise accustomed to brave the scourge of the four winds of heaven.—*R. G.*

Miscellaneous.

Culture of the Double Rocket.—The double garden Rocket (Hesperis matronalis flore albo pleno), is one of the most interesting plants we have. Although it is three centuries since it was introduced from Italy into this part of the world, it has still a great number of admirers, although it is very capricious as regards soil, and rarely lives many years in most gardens. I have cultivated this plant for many years, and with much success. It is true, that the soil of my garden is considered to be particularly favourable for its culture; nevertheless, I am convinced that if particular care were not bestowed on the plant, as I shall point out farther down, the soil alone could not secure us against the loss of our plants. I consider it quite hardy, little affected by light or shade, not caring whether the soil is stiff or light, damp or dry, and able to support any degree of cold. It has many enemies, but, if I am not mistaken, one only that is fatal; if haste is not made to prevent its bad influence, this enemy will soon destroy the plant, which seldom escapes from its attacks: I therefore regard the Double Stock as an ungrateful plant, which makes an ill return for all the care that is bestowed upon it. The enemy in question is the larvæ of an insect, at present unknown, which probably deposits its eggs in the stem of the plant, or even in the crown from whence the young shoots proceed. These larvæ, when they are allowed to exist, eat out for themselves a way, till they come to the young shoots, which they infallibly destroy, along with the mother plant, the following spring. The latter appears, at first, to be sound and well, and the young branches unfold; but in a few days the leaves turn yellow and wither, the stem droops, and the interior, when examined, is found to be hollow, and gnawed at its base. It is often seen that at the same time the upper leaves are surrounded and held together by the threads of a little grub. People fancy that this grub is the cause of the death of the plant, but that is a mistake, for such grubs may be found upon either healthy or unhealthy plants, and in reality only eat the ends of the leaves, without attacking either the flowers or the stems. The destruction of the larvæ in question, at the right time, is therefore one of the most important things in the culture of the Hesperis matronalis; it is not difficult to effect, and does not require much attention; the little trouble that it occasions is well repaid by the success. Here is my method:—After the flowering, towards about the middle of August, cut off the stem close to the ground, for the purpose of exciting the root to make some shoots. About the end of September—a week sooner or later, according as the shoots are strong—take the plant entirely out of the ground, and separate the shoots one by one. That done, divide the old root in two by a vertical incision. If the inside is quite healthy, green, and full of pith, without circles or violet streaks, the shoots may be planted with perfect success. If, on the contrary—and it is generally so—the old root is hollow, violet or black inside, or only marked with circles and streaks of those colours, the shoots must be examined attentively at the part where they joined the mother plant; cut a little piece off, and you will always find, before you come to the first radical fibres, a little white curved grub the size of a grain of rape-seed. It must be killed, and then the shoot will become a healthy and vigorous plant. I have never discovered two maggots in the same shoot; nevertheless, all the shoots that the infested stock produces in the autumn will perish the next year. If by chance the grub is not found in some of the shoots which have the symptoms before described, they must not be planted among the others, for you may be sure that they will perish in the spring like those which might not have been examined; for the grub is often hidden and difficult to find. It is necessary that the separation of the shoots from the old stump should be done with care, to be better able to examine each; and if some are without roots they may be treated like cuttings, for they will soon produce roots. When the plants have made many shoots in the autumn, they may be again divided in the spring, either to multiply the number of plants, or more especially, to obtain stronger and handsomer bunches. To look for grubs in the middle of spring is useless, for there are none. Cuttings of three or four eyes, separated from the stem, easily take when they are placed in the shade, and kept moist; the best time to make cuttings, is when the lower flowers are over. When they are made later, we reject those which are hollow or violet inside; for although they make some roots like others, they are sure to perish in the spring. It is useless to winter old plants, for out of 20 stems which they may throw up, 18 at least will perish in the spring, and the remaining two will only bear insignificant flowers. Otherwise, the culture is so simple, that it is not necessary to say one word about it. Stagnant water in winter, and excessive heat in summer, alone kills them.—(*Annales de l'Association, Hort. de Prusse, xv. p. 77.*)—*Note.*—The insect which the author of this article indicates as the most destructive enemy of the Hesperis is the larva of a fly, called by Entomologists Anthomyia brassicæ. It appears to be the same insect that causes the excrescences that are sometimes found on the roots of Cabbages, and also [illegible] the spring of gardeners.—*Revue Horticole.*

The Common Heron.—The animosity prevailing against this fine bird arises from his frequenting the ponds for a few small fish. For this offence he falls a prey to the gun of the keeper, and the miserable emblems of his success greet the eye, nailed against the barn-door or other more convenient site. Thus, for the preservation of a few fish, is this noble bird allowed to fall a sacrifice to ignorance and cruelty. I remember a keeper anxiously in pursuit of one who had made his appearance on the edge of a magnificent piece of water, and ventured to plead, but in vain, for his preservation. The water in question was of such an extent, that vast indeed must have been the congregation of these birds to have made any serious diminution of its inhabitants.—*J. M.*

Pot Drainage.—We have received from a correspondent "A." at Lincoln, some samples of zinc clippings, cut circular, and punched full of holes, so as to serve for the drainage of the bottoms of water-pots. If they do not choke up, they will be very useful, because they will effectually hinder worms from drawing into the pots. Our correspondent assures us that they answer the purpose perfectly.

Stones made Buoyant.—A stone crossed the Firth with the S.W. wind of the 5th. A single plant of seaweed had grown upon it, and, being covered with numerous air-bladders, migrated with the stone to the north shore. Upon being lifted out of the water, the stone weighed 3 lbs. 11 oz., and the material of the plant 2 lbs. 3 oz., making in all a weight nearly of 6 lbs., which the buoyancy of the air inclosed in a multitude of small pods had safely ferried over. The plant did not seem to be loaded to its full floating power; although some of the pods had been injured and some burst, enough remained entire to transport the stone, thus suggesting an idea to all makers of floating jackets, chairs, and other contrivances to be used in shipwrecks, never to inclose the air in one mass, but in a great number of subdivisions, each watertight, and containing each a number of little balls filled with the gas. A slight injury, such as perforation of a pin, may now render the best Macintosh-floater fatal. Not so, however, with the algæ when they go a-sailing, and execute on a small scale what icebergs are said to have performed in transporting the large boulder stones over the globe.—*Caledonian Mercury.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Almost all the soft-wooded stove plants that can be grown into large specimens by one or two seasons' growth, like Pelargoniums, may be conveniently treated like that popular tribe; cut them back after they are done flowering; keep them dry for a week or ten days, and then shake them out of the mould; shorten their large roots, and pot them in light rich compost in as small pots as their roots can be got into. This is a good time to look over a collection for this purpose. Where a large conservatory is to be kept gay all the year round, this class of stove-plants is by far the most useful to cultivate, as you can always winter them in little room, whereas fine woody plants will soon get too large and take some years before they are fit to appear in a good conservatory. Another great advantage is, that as soon as you get these plants established in the new pots, they will only require to be kept in that condition through the winter, and therefore will not require more than 50° of heat for three or four months.

Conservatory.—Pelargoniums that have been struck from cuttings early last March, and planted in the reserve garden early in June, should now be fine plants for flowering late in autumn, their first attempt at blooming in the open ground has been checked, of course, and now as their second flower buds are well formed they may be taken up carefully and re potted. Some people commit a great error at this stage, by putting such plants into heat at once; this should never be done; the grand point is to keep the leaves as free from excitement as possible, until the roots get hold of the new soil; a cool close frame covered with canvass is the best place for them; but in the absence of this, the north side of a wall or hedge will do; sprinkle them over the leaves twice a day, and in ten days they get over the check, without losing a leaf. Chrysanthemums and all other plants that are planted out for a summer's growth—a very excellent practice—should be treated in this way, and should not be allowed to remain in the ground too late; keep the conservatory dry from this time, and little air is required, except for keeping down sun-heat, now that the growth of most plants is nearly over.

Pits, Frames, &c.—There are many of the new Verbenas that will force admirably through the winter, with little heat; this is the time to get a supply for this purpose. The new Veronica speciosa also forces well for early spring, and although nearly a hardy plant, will stand as much heat as an Ixora. Pentas carnea and Manettia bicolor will answer likewise, and all lovers of the lovely Chinese Azaleas, who can afford it, ought to have the new varieties of them mentioned last May and June. The Nurserymen have been very successful in propagating them, and they may now be had reasonable. The old Locelia is as much sought after as if it were a plant of recent introduction, a proof that it is not a long liver under cultivation; it flowers freely in loam, but for pot cultivation and in the hands of beginners hardly any loam should be used; equal quantities of peat, leaf-mould, and sand will keep it in good condition for many years. When it is growing freely it can hardly have too much water, therefore it should have a good drainage, and ought to be under-potted. Every one knows by this time that it grafts as freely as an Apple-shoot on several stocks.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

Before the propagation of plants for turning out is proceeded with to any material extent, it is as well that a proper arrangement should be made as to what number of plants are required in another season. To keep up the interest of a garden, especially if planted on the grouping system, requires some considerable skill and forethought, to vary the scene in each succeeding year so as to prevent the arrangement becoming monotonous. Thus if warm colours prevail to any material extent this season, it would be as well to introduce a majority of cold colours next season and so edge each bed of the latter with its complementary warm colour. Indeed the system of edging beds with contrasting colours imparts a highly interesting feature to the flower-garden, and more especially to such beds as may be distributed over the lawn without any methodical arrangement. For these purposes the plants are so well adapted as those which have variegated foliage, and for that reason a large stock of variegated Pelargoniums should be provided. The best of these is Mangles's variegated, the common and golden variegated, and the different varieties of the variegated ivy-leaved Pelargoniums. The tree-scented varieties are an interesting variety, as is also a very dwarf variety called Dandy. This variety makes the neatest edging or a small bed of any plant that I am acquainted with. Of common Pelargoniums some of the best for beds are the Duchess of Orange, Alexandrina, Oliver Twist, Coronation, Gentilité, Ellen, Sidonia, Gipsy, Garth's Perfection, and most of the very free blooming varieties. Of the Oak-leaved kinds, Mowle's Victory is very neat, Rollisson's Unique also makes a fine bed, and the old Fair Ellen is not without interest.

Bedding.—Attend particularly to the regulating of overgrowths, especially in Petunias and strong-growing Verbenas; keep them well out in so as to form neat beds, and yet do not let them be any appearance of their having been cut. Mow, sweep, roll, and keep all neat and clean, and if there is any worm-casts in the walks water them with lime-water.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Carnations.—Layers must be regularly and carefully watered whenever dry weather makes it necessary, and all weeds should be removed as they appear. Those who layered their plants early will have many sufficiently well rooted to remove. Amateurs and others commencing the cultivation of these beautiful flowers (and they are, we are happy to find, on the increase), will do well, as we before have urged, to obtain their layers in good time. The following list of very fine varieties we have proved, and recommend them with the greatest confidence to young beginners; and those growers who do not already possess them should add them to their stock:—*Scarlet Bizarres*: Elliot's Duke of Sutherland, Hepworth's True Briton and Gameboy; *Crimson Bizarres*: Ely's Lord Milton, Wakefield's Paul Pry, and Greasley's Lord Brougham; *Scarlet Flakes*: Buckmall's Ulysses, Greasley's Marianne, and Wilson's William the Fourth; *Purple Flakes*: Brabbin's Squire Meynell, Pollard's First-rate, and Ely's Mango; *Rose Flakes*: Ely's Lovely Ann and Lady Ely, with Hudson's Lady Flora; *Red Picotees, light-edged*: Sharp's Hector and Gem, and Wood's Queen Victoria; *Heavy-edged*: Jessop's Sir William Middleton, and Sharp's Wellington; *Purple Picotees, light-edged*: Brinkler's Perfection, Gliddon's Vespasian, and John's Prince Albert; *Heavy edged*: Dickson's Trip to Cambridge, Sharp's Invincible, and Musson's Charlotte; *Light-edged Rose*: Gliddon's Favourite, and Bernard's Mrs. Bernard; *Heavy edged*: Green's Queen Victoria, and Wilson's Fanny Irby. *Ranunculuses.*—Seedlings in pans or boxes, which ought to have been kept growing as long as possible, should now, if the Grass is withered, be taken up; this must be done with great care, as many of the roots are very minute. *Dahlias.*—Earwigs are more than usually annoying: small pots in which a little dry Moss is placed may be fixed on the supports, and examined every morning.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—The cloudy weather that has prevailed of late has been favourable for the plants lately repotted. Those which are found to have commenced rooting may have air admitted as usual, and shading may be dispensed with. If the surface of the soil is exposed to the atmosphere it will be necessary to water occasionally; but if covered an inch or two with tan nothing more will be required than syringing over the leaves on the afternoons of fine days. Pay attention to the pits heated by dung, turning and renewing the linings, when the heat is found to be declining. Take an early opportunity before winter of laying in a stock of soil, if it be not already done. Choose the turf about two or three inches thick, from a field or common where the soil is of a firm, loamy nature. It will be in good condition for Pine-growing by February, if laid up now in narrow ridges in a dry, airy situation, where the sun and wind can act upon it. In October, after a few drying days, it may be thatched with dry Fern, or, what is much better, covered with a moveable roof, slanting both ways, to throw off the rain, and supported by posts at the corners sufficiently high to allow of a current of air passing between the covering and the soil.

Vineries.—The Vines intended to be started in November may be pruned now, if the leaves are fading. Do not shorten the spurs of these too much, as the chances of their showing well are very much less than if they were not to be started before the end of January; and by leaving two or three eyes there is more certainty of a regular crop; and it is easy to rub off the top buds at any time, if the bottom ones show. Prune also the Vines in pots, for early forcing. There are few better purposes to which any spare lights can be applied from this time till the Vines are started than placing them over the borders to keep them dry; and if a board is placed on edge under the lights, so as to exclude the cold air, a great deal of heat may be accumulated in the soil by the end of October, when the lights should be removed, to give place to a good thick thatch of dry Fern. Something of this kind, if well done, would contribute much to the success of early forced Vines. The wet weather, after the long drought, has caused an increased growth in most late Vines, and care must be taken not to stop the laterals so much, as to cause any of the principal eyes to start. Be careful to prevent drip, and persevere in guarding against damp, from whatever cause, where ripe Grapes are. I do not recommend the top dressing of Vine borders, at this late period, so long as the Vines are growing; but as soon as they are pruned, let a mixture of the best dung, chopped turf, and road-scrapings, be laid on the border, to assist the Vines in the following season.

Peach-houses.—The trees in the early house have now completed their growth, with the exception of an occasional rank shoot or two, which should be stopped as often as they start. Let the surface of the inside border be loosened up, and as much of it removed as possible without injury to any of the fibres. Replace this with a mixture of half-decayed turf, from a rich pasture and soot—eight barrowfuls of turf to one of soot.

Figs.—Where Figs are on the back wall of a late Vinery, let them on the first fine day have their final watering for the season, as it will be injurious to the Grapes to moisten the soil beneath them after this time.

Strawberries.—If the earliest laid plants have filled the pots in which they were laid, cut the runners, and a few days after shift the plants into six-inch pots, using a compost of decayed turf and dung, laid together two years previously. Stand the pots in an open situation, on boards, or slates, or a preparation of ashes, to prevent the ingress of worms.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Strawberries.—Proceed with making fresh plantations, choosing well-rooted runners, or such as have been taken up and pricked out in beds previously. It matters little whether they are planted in beds or in rows, provided the plants have a sufficiency of room. The ground should be well trenched and manured, and if the soil is of a stiff nature, the addition of a considerable quantity of gritty matter will be of advantage for keeping the ground open, as no spade ought to be inserted among them until they are finally dug down. For general purposes, no sorts are preferable to Keen's and the Elton Pine, and by planting on different aspects they will furnish a very early by planting on different aspects they will furnish a very early and a very late supply. Some of the new sorts I have not seen, and of others, such as Myatt's British Queen, I, as well as others, have got a spurious kind. Other sorts that have come under my notice are not comparable to the above two sorts, when both flavour and productiveness are taken into consideration. Rows or beds intended to produce next season should now have all their runners removed, and the plants thinned out, that the buds left may be fully matured. By adopting the latter practice, and surface manuring, one plantation will produce plentifully for a series of years, though this is not generally desirable, as it would interfere with a rotation of cropping.

Cucumbers.—Those on ridges have generally done well this season, but we cannot expect them to do so much longer, unless there are means for protecting them. Take every opportunity of securing bearing material to keep in a healthy vigorous state there is reason to expect. If you can command plenty of dung you may think yourself very fortunate; but if the making more of it, you have not a very large mushroom-bed, you will not think

of taking any vegetable matter, capable of undergoing that fermentation, to the vinous heat, which it has lacked while in the trance-ground state, a drop of these will sometimes make their fermentation [illegible] of us. It is of little use cutting them down and leaving them [illegible] of having them conveyed to the rubbish heap, as many do, when, though scarcely in bloom, certain constituents enough of their stems for the perfecting of their seeds, said this, nevertheless, take care to insure us with a supply next season. The method I adopt is to have all weeds in flower carefully conveyed to any building where there is a strong heat, which I find sufficient to destroy the germinating powers of the seeds of our common weeds. *Mushrooms*—Where a heat is wanted stirring, and there is no hall exhausted linings to go to, get some good fresh dung from the stables, re[illegible] the very longest; make a bed from a foot to 18 inches thick, where you can protect it from rain; beat it firmly, and as soon as the heat rises here it with holes all over; watch the bed carefully, and as soon as the heat gets about milk warm fill the holes nearly full, wait to see if it does not heat again too violently, and then spawn and earth up as usual. Fine Mushrooms will be thus produced, but much judgment will be requisite to spawn at the proper time.—*R. F*

VI.—ARBORICULTURE.

Old Woods—For the ordinary routine, refer to directions given in late Nos. Make preparation for any additional planting that is contemplated, by hoeing or trenching the ground; this should be done in autumn where the soil is dry, but in cold and wet situations spring is the best time for the operation.

Coppice—Attend carefully to young shoots from stools that were cut over during last winter and spring; regulate, thin, and train those shoots that are growing vigorously; pinch the ends off the weakest shoots, and reserve only as many of the strongest as will be required for use. I prefer shortening the supernumerary shoots to taking them clean out, for the first and second year, as it prevents them in a great measure from being so easily broken off by wind, or barked and bitten off by hares and rabbits. A stake and bandage will be often required in order to secure an upright leader to any favourite tree or plant that has been headed off, or otherwise lost its leader; many trees that have been injured or deformed might be effectually recovered by a little attention.

Young Plantations—Prepare ground for new plantations, if wanted, by inclosing, trenching, or hoeing. Remove any dead plants, (of which I fear there will be plenty this year,) and expose the soil to the atmosphere until the season for planting arrives.

Nursery Work—Attend to the directions given in No. 32 of the *Chronicle*.—*W. B.*

VII.—COTTAGERS' GARDENS.

About this time, when the hues of autumn begin to make their appearance, and symptoms of the year's decline to press upon our attention, the cottager should particularly attend to neatness in everything about the garden, and endeavour to preserve the beauty of the flower-border as long as possible. Keep all plants in flower neatly tied up, and remove their flowering-stems as soon as they become unsightly, if this is properly attended to, the flower beds, which are now in their highest state of perfection, will for some time to come amply repay the labour by their gay appearance. Dahlias, which are now coming finely in to bloom, should be occasionally supplied with liquid manure; keep them neatly tied, and see that the early ones do not pinch them. For entrapping earwigs nothing is better than bean stalks; place short lengths of them amongst the branches, examining them every morning, and killing the insects collected. Look over beds of Verbenas, &c., and assist them in regularly covering the space allotted for them by pegging them down on any vacancies that may yet remain to be covered. Cuttings of scarlet Pelargoniums, Verbenas, and other plants for bedding out, should, as mentioned last week, be got in as speedily as possible, in order that they may become well rooted before winter. Growing crops still require to have the soil well stirred between the rows with the hoe, not only to kill weeds, but to prepare and loosen it for being drawn to the plants as they advance in growth. Where circumstances have prevented winter Greens from being earlier put out, they may still be planted, as vacancies occur by the removal of other crops; but the sooner they are planted out now the better.—*J. M'H.*

State of the Weather near London for the week ending Aug. 20, 1846, as observed at the Horticultural Garden, Chiswick.

Aug.	Moon's Age	Barometer Max.	Barometer Min.	Thermometer Mean	Thermometer Min.	Thermometer Mean	Wind	Rain
Wed.	19	0	29.918	29.668	77	57	67.0	W	01

Average			29.815	29.687	71.0	50.1	60.6		

Aug. 19 Clear and very fine; densely clouded at night.
— 17 Cloudy and fine; slightly overcast, clear.
— 18 Overcast; very fine the night out, fair throughout.
— 19 Clear, very fine slight shower in the evening.
— 20 Lightly overcast fine cloudy all night.
— 21 Clear, cloudy and fine; overcast and mild.
— 22 Morning fine with light clouds; dark clouds in afternoon, cold at night.

Mean temperature of the week 3 deg. below the average.

Result of the Weather at Chiswick during the last 18 years, for the ensuing Week ending Aug. 31, 1846.

Aug.	Average Highest Temp.	Average Lowest Temp.	Mean Temp.	No. of Years in which it Rained	Greatest quantity of Rain	Prevailing Winds							
						N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.

The highest temperature during the above period occurred on the 29th and 30th Aug., 1826—therm. 88°; and the lowest on the 30th, 1827—therm. 39°.

Notices to Correspondents.

ANTIRRHINUM.—*A. Z.*—Your seedling is a good variety, but not a new one.*

BEES.—*E. B.*—We cannot afford to this subject more space than it at present occupies, nor do we think it desirable to do so. If the information contained in our columns from time to time is not enough, you should study some such writer as Bevan on "The Honey-Bee."

BOOKS.—*J. W. J.*—Stephens's "Book of the Farm," Loudon's "Suburban Gardener," Mackintosh's "Greenhouse and Flower Gardener," Lindley's "Theory of Horticulture."

CHRYSANTHEMUMS.—*A. B.*—These will be satisfactorily benefited by Potter's Guano if it be mixed in the soil. The quantity necessary for each plant depends much on the condition, and the size of pot in which it is growing. When a plant is in good health and growing in an 8 inch pot, which is the size generally used, 1 oz. or 1½ oz. may be mixed in the compost.

CAPE HEATHS.—*A Subscriber*.—The following are named kinds, and may be easily procured, viz.—Hartmanii, pink; Aristata major, red; Accumiata longiflora, purple; Tenuiflora, white with pink shade; fastata, white; Archeriana, scarlet; Depressa, yellow; Elegans, light purple; Cavendishii, yellow; Mundsleii, light purple; Retorta major, pink; Lamprosi regia, flesh-coloured; Hyemalis, purple, tipped with white; Tricolor, red; Linnæoides superba, purple, with white tip; Jasminiflora alba, white, and all the varieties of Ventricosa.

GRAPES.—*J. R.*—The premature decay of the shanking and dropping of some of the Berries of your Muscat Grapes is doubtless an important supply of nourishment. This may be owing to various causes; the border may be at present too dry, and the roots may have previously suffered from cold and wet; or the foliage may have been too scanty, or too unhealthy for contributing a due share of elaborated sap for invigorating the roots in the preceding season.

GOOSEBERRIES.—*A. B. M. M.*—The following are the names of 12 of the finest flavoured:—Red Champagne, Red Warrington, Red Turkey, Keen's Seedling, Warrington, Yellow Champagne, Heaborn Green Gambo, Crumpled Champagne, White Fig, Woodward's Whitesmith, Taylor's Bright Venus, Early White, White Honey.

INSECTS.—*Q. Q. Q.*—Your caterpillar is possibly the Noctua meticulosa; but have the goodness to tell us what mischief it was committing. Did it destroy your Carnations, and if so, in what way? *R.*—*Green Horn*.—You should have sent us specimens. We recommend hand picking, also your perusal of the 4th vol., p. 100, of the "Royal Agri. Journal," where the subject is discussed. *R.*—*H. A.*—The light-coloured aphides you will find described in the "Royal Agri. Journal," vol. iii. p. 49, but we cannot be certain of the species, as there are no winged specimens. The black ones are possibly the Aphis Fabæ but as you do not say what Beans they are attacking, we cannot advise you as to a remedy. *R.*—*A Subscriber*.—If you will apply to any chemist, he will supply you with a liquor which will attract and destroy all your house flies. *R.*—*G. R.*—Your grubs will change to Dilophus febrilis; we imagine they feed upon the roots of plants, but whether they will affect the health of your Pelargonium we cannot say. *R.*

LOCAL HORTICULTURAL SOCIETIES.—*A. B. C.*—We cannot interfere. It seems injudicious but circumstances may *possibly* render it advisable, though not probably.—*A Gardener, Dartmouth*.—We must beg you to excuse us. Anonymous discussions cannot be carried by us any further than they have gone, but must be settled on the spot. We are too far off to sift out the truth, which is, moreover, of no *public* interest.

MANDEVILLA SUAVEOLENS.—*A. B.*—This may be easily propagated by cuttings of young wood, either now or in spring. Insert the cuttings in silver sand, cover them with a bell glass, and give them a little bottom heat.

MANURES.—*A. B.*—For plants in pots, superphosphate of lime is most suitable when diluted in water at the rate of 1 ounce to 3 gallons. For Fuchsias, Pelargoniums, Chrysanthemums &c. this may be repeated every three weeks or a month; but for others, such as Epacrises, Heaths, &c., once or twice during the season is quite sufficient.

MELONS.—*B. B.*—The Beechwood is a much-esteemed green-fleshed Melon.—*M. D.*—You will doubtless find that your Melon plants, grown above a hot water tank and from which the fruit is now dropping are too dry at the roots.

MONSTROSITIES.—*An Irishman*.—Such instances as yours are not uncommon. That in the annexed woodcut is a similar instance. They are buds assuming the appearance of Potato-tubers, and proving the latter to be gouty branches. The cause of their appearance is uncertain.

MULBERRY.—*B. B.*—You must sparingly cut the roots of your Mulberry tree against a wall just before the leaves fall in autumn. Pinch the shoots in summer, so as those near the base may have plenty of light to enable them to perfect fruit buds.

NAMES OF PLANTS.—*W.*—Alstroemeria Ligtu, and a very fine purple variety of A. pelegrina.—*Col.*—Not an Orchidaceous plant, but Lycopodium lepidophyllum. Your specimen is dead. The species is not known in cultivation.—*Derby*.—Psoralea pinnata.—*E. R. I. F.*—Malva Munroana.—*S. W.*—Amaryllis tenella, and Hallo a nigra.—*Indiana Meta*.—Lycium barbarum. For colours you must apply to the dealers in them. In flower painting every kind of tint is occasionally required. All the advice we can give you is not to use Prussian blue, or any metallic colours.—*T. Cripps*.—Either Trifolium minus or tuberosum.

NAMES OF FRUITS.—*A. B.*—The Apricots were too far gone when received. No. 1 only could be judged to be the Moor park from the perforation along the edge of the stone. Plums: 2 Azure Hative, 4 Drap d'or, 5 Fotheringham.—*A. B., Fulham*.—No. 1 appears to be the Nectarine Plum; 2 Washington.—*J. B. M. H.*—Gooseberries.—No. 1 appears to be Red Turkey; 3 Ironmonger, not Red Champagne; the latter grows very upright, and its fruit is more oblong and not so dark coloured as that of the Ironmonger; 3, Ashton Seedling, same as the Red Warrington; 4, Early Sulphur; 5, Red Walnut; 6, Crystal; 7, Golden Drop; 8, Probably the Amber.—*W. S.*—The Plum you found in a hedge row, where it must have been planted and which flowered in February bearing abundantly, though in a bleak place and very barren soil, is the Myrobalan or Cherry Plum. Its uses have not been fully ascertained. It would probably answer for kitchen purposes.—*T. L., Kilmarnock*.—Your Apple is the Scarlet Crofton, a winter Apple.

PANSIES.—*An Irishman*.—Brown's Curlon, Pearson's Black Prince, Buxton's No pius Ultra, Cook's Mulberry Surpass, King's Sulphured Elegans, and Magin's Bridegroom. Sow your seed immediately.*

PEAR-TREES.—*B. B.*—If you stop the shoots of your Pear-trees, by merely taking off the extreme points in the beginning of June, and then shorten back one half of them to 6 or 8 inches at midsummer, and the remainder to the same extent in the beginning of July, the trees will most probably soon come into a bearing state; and if they do not, as subsequent growths will prevent root-pruning, you must have recourse to ringing.

PELARGONIUMS.—*W. J. R.*—The Polemonium you mention, when it comes true, is one of the best for cultivation; the form, size, substance of petal, and the size of the petals when fully expanded, constitute it a first-rate flower. In colour it is fine also, but, unfortunately, there is with it the flower a strong disposition to spot. During the past season more particularly, not half the flowers were true. It is too early to answer your other question; lists of the new flowers not being yet sent out.

THE PINE SCALE.—*B. R.*—We quite agree with you that if your gardener has really discovered some certain and simple remedy for this insect, he deserves to be rewarded; and we have no doubt that advertisements would procure him plenty of customers. The difficulty is to try it. The Horticultural Society does not cultivate Pines now; but the remedy would probably destroy other scales as well as that of the Pine Apple; and if so, its value would, of course, be the greater. If you wish it, we will have the experiment tried; but your own testimony would surely be sufficient to satisfy persons of the efficacy of the means employed.

POTATOES.—*A Subscriber*.—Never soak Potatoes in water before quickly them. If it be deemed requisite the water should be poured off, and the Potatoes set on one side of the fire to dry, before they are peeled. That is the way to have them mealy. Steaming them is a still better way. Never cover them up after they are ready to be dished up.

SAND.—*Wallenste*.—Certainly use sand, if well washed, may be employed for all plants that do not dislike lime; but as it always contains considerable quantities of small shells, it is on that account unsuited for some things. Pit sand, although reddened by oxide of iron, is better, if well washed. Fine white pit sand is best of all; but it, too, is apt to bind if used in large quantities. Roadside sand always binds—we suppose because it is angular.

STRAWBERRIES.—*S. S.*—The distance between the rows of Strawberries should not be less than 2 feet, and from 12 to 18 inches from plant to plant in the row, according to the vigour of the variety and richness of soil. Yours being planted 9 inches apart each way, if they are Scarlets you may dispense with every other row; if Pines, every other row as well as every alternate plant in the row.

VINES in a Greenhouse.—*D. G.*—As you do not wish to force the Vines in your greenhouse, no fire in winter is required on their account. Having been only planted this spring, they should be cut back to a few eyes in autumn, and not allowed to bear in the ensuing season.—*J. F. C.*—The characters of the Vines you mention are not known.

MISCELLANEOUS.—*A Constant Reader*.—Keep your Caladium bicolor during winter in a pot where it gets very little water, and replace it in the tank next summer when it is beginning to shoot again; having previously got it by degrees into good growth.—*R. N.*—The sizes of flower-pots vary considerably in different parts of the country. The dimensions of the different sizes in the neighbourhood of London are given at p. 331 of the volume for 1844.—*W. C.*—Brachycoma latifolium is a very short trailer, with deep dull crimson flowers. Kennedya or Hardenbergia Comptoniana, is a plant of great beauty, which will grow to a considerable size if permitted. A temperature of 50° is too high in winter for most greenhouse plants.—*F. D.*—We really know of no means of distinguishing correctly stove and greenhouse plants. So many species can be cultivated with more or less heat, that all positive distinction is broken down. For this reason the Horticultural Society of London has always found it necessary to allow them to be shown in the same class. The Achimenes, for example, will grow, and in considerable beauty, in a greenhouse, though it does best in a stove. Suppose a man starts it in a Cucumber frame, which he can easily do, and then transfers it to a good well managed greenhouse, who could then say it was a stove plant? In truth, all plants that go to rest in the autumn losing their leaves, may be cultivated in a good greenhouse if once fairly started. Is a Balsam a stove or greenhouse plant?—*Oulton Hose*.—The Number you want to complete your set is out of print.—*D. C. L.*—We can hardly deal with the condition of the New Forest without a personal inspection. If we can manage it, we will pay Hampshire a visit this autumn, and, in that case, give our opinion.—*Dud's*.—Walnut trees have probably been dying from their roots being in a cold wet bottom.—*Subscriber*.—We are not able at present to recommend you what new Pelargoniums to add to your collection, the lists of the new sorts not being all published.*—*A Reader of the Chronicle*.—Your specimen is a curious sport, and forms an illustration of morphology.*—*X.*—Plants of Salpiglossis should be treated as tender annuals. They should be raised in heat, and should be potted off singly into small pots as soon as the first rough leaf appears; afterwards they should be kept warm and rather moist. If allowed to grow large before they are potted or removed from the seed-pot, they are almost sure to become sickly, or die. They require a soil composed of sandy loam and a little leaf-mould; and great attention should be paid in watering them. Purge may be cut any time between November and March. Ten week Stocks may flower if the autumn is mild; but they will be worthless, as the colours always run. Keep Heaths that are just up in the seed pots until next spring, place them in an airy and rather dry situation. Keep the bulbs of Lilium tigrinum in the pots until spring. Nos. 13 and 14 for this year may be had.¶—*A. S. Y.*—We have on several previous occasions stated all we know of the Patent Asphalte Covering; namely, that it is light and warm, tight, and will, apparently, last for some years, if properly fixed and painted. We never recommend one dealer in preference to another.

SEEDLING FLOWERS.

CALCEOLARIAS.—*W. H. M.*—Of your seedlings 10 and 11 are bright and high coloured, the latter a self bright brown, the former having a rich velvety brown spot, with a margin of very bright brown. Both these flowers are well formed, but rather flat in front. 6, cream, with large crimson spot; 1 and 3, yellow grounds with brown spots, good in general form but too flat; 7 and 8 are very pretty, but too small for the present advanced state of this flower. 10, 11, and 8 are the most desirable.*

FUCHSIAS.—*J. Y.*—Both your seedlings have rather coarse sepals, and the difference is too slight between the tube and corolla; they are stout bold flowers, but not equal to the best sorts cultivated.*—*W. W.*—The variety most worth preserving among the sorts sent up is No. 219, the colours are very distinct, and the form of the flower elegant; 218, which is somewhat similar in colour, is neither so bright nor so graceful in form; 220 and 217, very large, but coarse in the sepals, and not distinct in colour; 222, bad form; nor do any of the other sorts appear sufficiently novel or distinct in colour to bring out as new varieties.*—*E. B.*—Your seedling from *F. splendens* does not appear sufficiently novel to recommend it for general cultivation, it differs from others principally in the brightness of the tube; the foliage is rather large and heavy.*—*J. W. Vectis*.—The distinction you point out in your seedling is looked upon as a defect.*—*J. J.*—No. 1, sepals coarse, and the colours not sufficiently distinct; 2, the divisions of the corolla are too narrow—they unfold and remain separate; 3, too coarse in the tube and sepals.*

PENTSTEMONS.—*J. J.*—The bigeotia arrived in good condition. The flowers are rather coarse, and the purple appears uncertain; it too much resembles a dash of colour in the corolla.*—*Curator*.—The best and most distinct of your specimens are 3, a deep mottled variety; 2, a clear, bright, rosy crimson; and 6, having a light ground with dark veins. 1 and 4, though good flowers, are not so much in colour; and 5, a deep, rich, mottled crimson, we have seen in other collections, but not so large; this, and No. 3, appear disposed to break into more decided colours.*

VERBENAS.—*S. S.*—Your seedling, to be, indeed Queen of England.—Rosy pink, with yellow eye, is a large and magnificent variety.*

*** As usual, many communications have been received this week.

LIQUID MANURE.
ENGLAND INDEPENDENT OF THE WORLD FOR CORN

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.
The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 69, Dorset-street, Fleet-street, London

The Agricultural Gazette.

SATURDAY, AUGUST 24, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.
THURSDAY, Aug 29 Agricultural Imp. Soc. of Ireland.
THURSDAY, Sept. 5 Agricultural Imp. Soc. of Ireland.
FARMERS' CLUBS
Sept. 2 Usk. | Sept 10 Aberguvenny.

THE condition of AGRICULTURAL MECHANICS in a country is the best possible criterion by which to estimate the character of its cultivation—for this must be carried to a high pitch before a demand can exist for well-constructed and efficient, but necessarily expensive implements; and thus the improvement which has of late years taken place in British Agriculture is in nothing more satisfactorily apparent than in the superiority of our present farm implements over those formerly in use. Scarifiers and cultivators have now, for many purposes, taken the place of the tedious plough; drilling-machines, as well as machines for scattering seed broadcast, have taken the place of manual labour; the threshing-machine has been substituted for the flail; and chaff-cutters and Turnip-cutters are generally used where such implements were formerly unknown.

Although these substitutions have not all been effected within the last few years, yet any one who has had the opportunity of attending the Annual Meetings of the English Agricultural Society, and of comparing the implements there exhibited from year to year, must acknowledge that great improvements have taken place in the Mechanics of Agriculture even within the still short period of that Society's existence. Speaking of the exhibition of implements at Derby in 1843, the Editor of the *Gardeners' Chronicle* last year made the following observations:—"The most rapid strides have been made in this department. The show of implements at Oxford was not very good; nothing very new or perfect was exhibited there. At Cambridge it was much better; Liverpool and Bristol surpassed the preceding; and at Derby there was the greatest collection of every kind of implement—from the simple plough to the portable steam-engine—which had ever been brought into one spot. For three days we spent many hours delightfully in following the new inventions and the improvements pointed out by the different makers; and many more days would have been required to notice all that was worth the attention of the agricultural mechanician."

Our Report some weeks ago of the Exhibition at Southampton shows how far this rapid progress of improvement has been sustained.

Those who have been unable to visit the show-yards of the Society at its Annual Meetings may easily estimate the extent of this improvement by comparing the works which have been published on the subject. The latest of these, that by Mr. J. Allen Ransome, of Ipswich, is incomparably the best that has appeared; it is descriptive of a greater variety of better implements than any of its predecessors, and it exhibits a thorough acquaintance with the principles on which the efficiency of the different machines depends. We shall have opportunity, in the course of future Articles on Agricultural Mechanics, of noticing Mr. Ransome's opinions on various farm implements; and it is therefore unnecessary at present to refer particularly to his descriptions of them. In illustration, however, of the improvement in them to which we have been alluding, we take the liberty of extracting the following remarks on their condition centuries ago:—

"In our own island, ploughs were, during the early and dark ages of its history, rudely constructed, intolerably heavy, and of all kinds of shapes; a result which might have been reasonably anticipated, for by an old British law, every ploughman was required to make his own plough. The harrows, and other agricultural implements, were equally ill-shaped. Drills were utterly unknown until about the sixteenth century; and when, about the year 1730, the celebrated Jethro Tull endeavoured to banish the flail from the barn, his neighbours loaded him with execrations. The tradition of the neighbourhood of Prosperous Farm, near Bungerford, which Tull cultivated, still is, that he was 'wicked enough to construct a machine, which, by working a set of sticks, beat out the Corn without manual labour.' This is the first traditionary notice of a threshing-machine with which I am acquainted."

The chapter on threshing-machines in this work—one of the best in the book—details the successive steps in their improvement since that period. We shall endeavour hereafter to describe, and fairly to estimate, the value of the various farm-implements now used, in the condition to which they have been brought by that process of improvement to which we have been alluding; and we are glad to be able to say, that in preparing these descriptions, and in forming these estimates, we have been promised the assistance of many eminent manufacturers—that of Mr. Ransome, among others.

WE have been asked by a correspondent if the practice suggested by Mr. Haunam, and detailed in a late Number of this Paper, on the subject of HARVESTING GRAIN CROPS, is applicable to Barley and Oats, as well as Wheat.

In the latter case this point has been already determined by almost universal practice—upon other grounds, however, than those indicated by Mr. Hannam's experiments. Oats are generally cut before their straw has lost its green colour, simply because, when left till quite ripe, they are very liable to shed their seed, its attachment to the stem being much slighter than that either of Wheat or Barley. Most probably, however, this practice is productive here, as well as in the case of Wheat, of a better quality of grain than we should otherwise be able to grow.

With reference to Barley, again, the almost universal practice is to let it remain on the field till it is dead ripe. Whether this practice be correct or not, Mr Hannam's experiments cannot, we think, be held to condemn it; they only determined the influence which the time of harvesting grain exerted on its quality *as food*. Barley being generally grown for malting, is seed to be sprouted, not grain to be eaten; and there is but little in the experiments to which we allude to indicate the effect of early or late cutting on the quality of grain *as seed*. On this subject Nature is as yet our only guide, and if it be safe to follow her, farmers are certainly right in permitting Barley to become thoroughly ripe before cutting it, for seed is naturally never shed or sown till dead ripe.

The practice, however, of permitting Barley to remain on the field till thoroughly ripe, has not, we believe, arisen from any notion of the propriety of imitating Nature in the matter, but from the circumstance that it is of importance in malting grain that it should all sprout together, so that the process may take place fully within the time allotted for it; and it is probable that the evenness of sample which is thus so essential in malting Barley can only be obtained by ripening it thoroughly. The only way to obtain grain all of the same stage of ripeness is to make it all dead ripe.

Whether, if it were possible, with our variable soil and irregularly sheltered fields, to cut the crop all in one stage of growth before it became thoroughly white, the quality of the grain for malting purposes would thereby be improved, remains an unanswered question.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(*Continued from page 562*).

Fullers' Earth.—Below the Bathstone lies a bed of clay, from 40 to 50 feet in thickness, in which, near Bath, the fullers' earth is found. This bed crops out below the limestone rock, under which it lies, and its course, dependent as it is on the windings of the hills and valleys, is most tortuous. It is, however, easily traceable along the lower edge of the Bath-stone. This bed of clay is generally of a yellow colour, and near and beyond Bath the fullers'-earth occurs in it in isolated masses, in search of which pits are dug at random. It throws out a great many springs; many streams take their rise from above it.

Agricultural Character of the Fullers' Earth.—The surface of the narrow band in which this bed of clay is exposed is most irregular. It may be easily traced at a distance by the contrast in this respect which it presents to the surface of the ground on either side of it. This unevenness is sometimes owing to the occurrence here and there of masses of debris, which have fallen from the rock above, but may be more generally due to the wide cracks made in the clay during the summer, and to the slight slips which consequently take place on the fall of rain. This bed of clay is of very little consequence in an agricultural point of view; it is not only of very little extent, being a mere band, but is steep, being situated on the side of the hills. It is almost wholly in pasture, and this pasture is of the poorest description. When left to itself, as in commons, it becomes covered with the Bramble, the Sloe, and the Briar, which are characteristic of clayey land in general. When arable the soil is very stiff and clayey. It is well seen at the top of a row of fields immediately below the road into Bath, as it winds along the edge of Charney Down. The soil is there a dark (nearly black) stiff clay, forming a narrow band along the upper edge of the fields, which are chiefly of a brashy soil, of a ruddy brown colour, overlying the rock of the inferior oolite. It is adapted for the growth of Wheat and Beans, but, in the few instances in which it is arable, it usually forms, as in the case just cited, merely a portion of fields, including both it and the soil on the rock below it, and thus seldom receives a cultivation peculiar to itself, only taking part in that of the whole field. Now, as the soil both on the inferior and the upper oolite, the one immediately below, and the other immediately above the clay of the fullers' earth, is of a brashy nature, and peculiarly a Barley soil, it is evident that the soil on the clay between them, receiving the same kind of cultivation as they do, can seldom be cropped and cultivated in a manner suited to it. It is only when a crop of Wheat is taken that this is the case, and even then it does not show that superiority as a Wheat soil that might be expected, being so wet that crops of no kind will succeed on it till it is drained. The clay of the fullers' earth, when it runs out on the inferior oolite below it, does not appear to produce that improvement which might be expected to follow the mixture of soils of such opposite characters. This is perhaps owing to the extreme wetness of the land during six or eight months in the year, the whole of the rain falling on the upper oolite being turned out by the clay, over the surface of which it runs until it meets the rock of the lower oolite, through which it sinks.

Inferior Oolite.—The member of the oolitic series upon which, in the descending order, we next come, is the inferior oolite. This consists of two beds, the upper a limestone rock, and the lower a calcareous sand. This rock comes out to the surface all along the edge of the hills, as will be seen by a reference to any geological map of the district. This limestone has much more of the oolitic structure than the upper limestone of the series. It is a softer rock, capable of being worked with the saw as well as the chisel, and is more easily worked for ornamental purposes. It does not, however, stand the weather well. The whitest and finest stone is found in the lower beds of this rock, the impurity of the limestone, owing to the presence of clay, increasing upwards. The uppermost bed, which varies from 20 to 30 feet in thickness, contains as much clay as lime. This top bed consists chiefly of large concretions of shells; it gets the name of *Rag-stone*. The lowest bed of this rock, that, resting on the sand, differs from the rest of it in not being much affected by the weather, is a weather-stone, and accordingly, in quarries and other sections, where both are exposed, it projects uninjured from the midst of the debris produced by the action of the weather on the rock above. This bed does not exceed two or three feet in thickness. Below the limestone rock, and of about equal thickness with it, occurs a bed of calcareous sand, generally of a yellow colour. This sand, in the neighbourhood of Wotton-under-edge, is ferruginous in a high degree, and presents a curious oolitic appearance, which is not common to it. There are also concretions and hardened masses occurring in the midst of it, generally in layers. These are provincially termed *Sand-bats*. They are owing either to a more indurated state of the sand, or to the presence in abundance of shells, of which generally there are but few.

Agricultural Character of the Inferior Oolite.—The soil on the lower oolite is of two kinds; that on the limestone rock necessarily differs from that on the sand. The one is very shallow, full of fragments of rock, and of a brown or ruddy-brown colour; while the other is a light sandy soil, partaking more or less of the yellow colour of the subsoil, according to the degree of cultivation it may have received. The stony brashy soil on the rock is generally situated on the steepest part of the hill-side; and being thus too steep for arable land, and too shallow for good pasture land, it is generally covered with wood. The Beech is the tree natural to the thin calcareous soil occurring on this rock. The valleys of Hawksbury, Wotton-under-edge, and Waterleigh, and a great part of the valleys of Ozleworth and Uley, are thus surrounded by wood. This is the case very generally along the whole of the oolitic escarpment, and some of the finest Beech woods in the kingdom are to be found here.

Where the land is arable, the practice of the farmers varies very much. Some take successive crops of Wheat and Potatoes, and thus sell everything off the land; others take Wheat, Potatoes, Barley, and fallow or seeds or Turnips, in succession; but whatever the principle be, if there be any which they adopt, whether it be good or bad, the mode in which they carry it in o practice and follow out the details of cultivation is slovenly. This is attested by the foul state of the land. The Barley and Wheat crops are, during the spring months, buried in Charlock, the wild Mustard, and a hundred other weeds.

The slovenly state in which this land is generally to be seen is, perhaps, owing to its being let in small farms, and to the practice of sub-letting, which is common, especially when the Potato crop comes round. To this, however, though it is general, there are exceptions. Even a bad system may, in the hands of an active farmer, be made the means of cultivating his land well. The soil on the sand is of a much more valuable kind than that on the rock. Where both exist in their natural state, as in the many commons occurring on this rock, a shower of rain, after a long drought, will enable one to trace to an inch the junction between the two; the Grass on the sandy soil becomes as green as the contrast which it presents to the withered herbage on the brashy soil can make it. The soil on the sand is chiefly in pasture, and some of the richest pasturage in the county is to be obtained on it; whoever has witnessed the freshness and richness of the verdure which the many beautiful valleys intersecting these strata present to the eye after a genial rain, will not doubt this. It also forms good arable land; and where this is flat, as in the case of Mr. Dimmery's farm at Stinchcombe, a report of which by Mr. Morton appeared in the first

volume of the Society's Journal, the land is most valuable. When situated on the hill-side, it is necessarily not so well suited for arable land; and in consequence of the continued practice of ploughing down hill, the tops of many of the fields thus situated have the soil entirely removed from them, and expose the yellow sand of the subsoil; this renders them still less valuable as arable land.

It is on this soil, in the Nailsworth Valley, that the only water-meadows occur that are to be found in our district. The following statement, with which the proprietor of these meadows favoured me, of the expenses and returns of irrigation in this particular instance, shows most conspicuously the advantage of the operation:—The extent of the meadows is about 15 acres. Before being irrigated they were valued at prices varying from 10*s.* to 3*l.* per acre and averaging about 30*s.* In the original state the land rented sheep, and was therefore unsafe, except to put fat sheep on just before going to the butcher The expense of building bridges, laying out and digging the water-courses, &c., in fact the whole expense of irrigation, amounted to about 15*l* per acre This is higher than is the case in many instances, owing to the number of bridges and aqueducts rendered necessary by the narrowness of the valley. The annual expense, including repairing the hatches, clearing out the water-courses &c., amounts to 15*s* per acre, to this is to be added 15*s* as the expense of harvesting the hay crop. The return from this outlay is in the form of a greatly increased value of spring and autumn feed, and also in the entire destruction of any tendency in the land to rot sheep The meadows are generally shut up during the first week in May, and the crop is cut in less than two months, it averages 35 cwt If it were allowed to grow three weeks longer, it would probably average 45 cwt per acre, but this would be at the expense of a deterioration in the quality of the hay and in the value of the latter-math The value of the early spring feed till May, and the autumn feed till December, is estimated at 1*l* per acre The following, then, is a statement of the profits per acre, per annum, arising from irrigation, in this instance —

Dr Cash	£	s	d
To 35 cwt of Hay, at 30*s* a ton	5	5	0
To value of spring and autumn feed	2	0	0
	£7	5	0

Contra Cr	£	s	d
By former value of the land per acre	1	10	0
By 5 per cent on out lay of 15*l* per acre	0	15	0
By annual expense of irrigation	0	15	0
By annual expense of harvesting Hay	0	15	0
Balance — profit per acre	3	10	0
	£7	5	0

To this is to be added the immense advantage to the farmer of being able to carry the crop off the land each year without injuring it. The manure arising from the consumption of the Hay-crop thus goes to enrich the fields of an arable farm in the neighbourhood. The good done by irrigation in this instance does not seem to be owing to the deposition of any soapy or oily matter which the water may occasionally contain from having passed through the mills higher up the valley. In an instance of a water meadow at Longfords, one of a series possessed by the proprietor of those just alluded to, there were two descriptions of water employed: the one contained the washings and sweepings, &c., of the streets of Minchinhampton, the market town in the neighbourhood, and the other was brought directly from a spring close to the field, the beneficial effects of irrigation were greatly more manifest in that part of the field over which the pure spring water* was used than in that watered by the washings of Minchinhampton This is certainly not the result which would have been expected, and it shows that land is benefited by the process, not so much by the deposition of sediment, as by the protection given to it during the frosts of winter.—*M.*

* It should be stated that the spring water was highly impregnated with the carbonate of lime.

ON THE APPLICATION OF MANURES

In former communications I expressed an opinion that the main uses of the roots of a plant were two-fold, the one to fix itself in the ground, the other to seek water. It is in search of water, and of that alone, that the young root in the first instance descends into the earth: did it seek other nutriments, it would rather remain near the surface, where such matters abound. But that Providence, which always works by the simplest means, where simple means are sufficient for the end, has by this one attraction made the root by fixing it in the ground, a holdfast also for the fabric over head The plant has no foresight of the necessity of securing itself in its position, but impelled by this powerful attraction to supply itself with the water necessary for the growth of its stem, its radicle shoots several inches into the soil to insure a supply; and before the plumule raises its head to seek the light of heaven, it has thus firmly established its hold on the earth. Does the existence of the attractive influence of water require illustration? A root has been uncovered, a wet sponge placed near it in a direction different from that in which the root was proceeding, the roots soon altered their position, and turned towards the sponge. The attractive power of water may be exemplified in other methods than those on the roots of plants:—When a wet sponge is held under the leaves of a tree, they bend down in order to touch it If a vessel of water be put within six inches of a growing Cucumber plant, in less than twenty-four hours the latter will alter its direction; the branches will bend towards the water, and never alter their course until they come in contact with it. Any root, not naturally fibrous, will become so if exposed to the action of running water. It thus increases in mouths, and the necessity no longer exists of striking its roots deeper into the soil. Liebig states, "Fruits, leaves, seeds, nearly every part of the plants of a former world, except the roots, are found in the brown coal formations." In that age of the world, when the alluvial formation of these layers took place, the surface must have been so moist as to preclude the necessity of plants sending their roots deep into the earth in quest of water; the roots were small and fibrous on that account, and not because of deficiency of carbon in the soil, as assumed by Liebig.

But it may be asked, Does not the same cause act on the plumule? I would say no; or rather, that it is counteracted by an opposite and stronger attraction, to which the plumule is by its nature more subject It is the attraction of light, and light alone (not heat, for the surface of the earth is warmer than at any distance from it) that compels the stem to rise into the air, it has no need to seek water, but it requires for all its purposes light, and by it the stem is brought into the region where all that is further necessary for the support of the plant is to be found—the gases of the atmosphere and the various effluvia which exhale from organic matters in a state of decay on the surface of the earth, or buried skin deep within her bosom That light has an attraction powerful enough thus to make the plant shoot upwards is a matter of every-day observation, the Pelargonium in the cottager's window sends out its branches to the light of day, it extends them not into the darker, though by many degrees warmer recesses of the chamber A very strong and curious proof of the attractive power of light offered itself to me in 1827, at Feahle in the county of Clare To ascertain the effect of certain steeps, I had sown some Oats in a small room into which the light was admitted by a single pane of glass, the stems tended in direct lines to this pane, but there happened to be a stone about 6 inches high in the direct line between the pane and some of them, all the stems so situated declined from the right line to the pane, from the perpendicular, and from the stone, and took such a direction as to strike the ray of light that proceeded from the pane over the stone at right angles, that is, they took the shortest possible line to arrive at the ray of light, and on reaching it curved directly towards the pane When seeds are sown too thickly, the plants are drawn up, according to the popular phrase—they are drawn up by the attraction of light, on the contrary, when the seeds are sown thinly and light is admitted around the plants, they spread out and become branchy

But requisite as the presence of light is to the growth of the stem, it is probable that its absence is as favourable to the growth of the root, there has long been a cherished opinion of the working gardeners and farmers in favour of sowing seeds in 'the darks," that is, when the moon reflects not the light of the sun (she does not reflect his heat) Martin Doyle cites (though he smiles at it) the authority of a Wexford gardener for sowing his Cauliflower seed when the nights are dark in the month of May We are too generally prone to scepticism when the extent of our reason falls short of the depths either of Revelation or Nature it is not impossible that popular belief may be here, as it frequently is better founded than we are disposed to admit Whether the absence of light be favourable or not to the germination of the root, as the dark nights are probably passed away when the plumule is fit to be acted on by light, the moon's full lustre may serve the plants essentially in this their early and it may be their more susceptible period of growth —*J M Goodeff, Revenue Police Granard Ireland*

ON SWING AND WHEEL-PLOUGHS

It is evident that the wheel has been an addition to the simple original form of the plough Whoever added it did so no doubt, with a view to its improvement, probably in order to assist his own imperfect management of it Again, there is no doubt but that an implement is perfect in proportion as its work is independent of the skill of him who manages it Upon this fact, those who prefer the wheel-plough found their first argument in its favour They say that it requires less skill for its management than the swing-plough does—that a boy may guide it This is, doubtless, true They say, in the second place, that the draught of the swing plough is greater than that of the wheel-plough This point, however, has not been so definitively settled by experiment, but that it will be fair to give the arguments of the opponents of the wheel ploughs on this point. These shall be stated in their place In the mean time, it may be said that, supposing the two implements to be guided each by a man of ordinary skill, the draught of the wheel-plough will at any rate be more uniform, and so far, easier to the horses. They state, in the third place, that the depth of the furrow is by this plough preserved constant and uniform, and is not liable to that irregularity which marks the unskilful ploughman. These, so far as I know, are all the arguments used by the wheel ploughmen. They are answered as follows:—To the second one, it is said that the draught of the wheel plough may be less in particular instances than that of the swing-plough; but it is not so as a general rule The plough may be so regulated as to "swim fair," though it be a swing-plough, so that he merely holding it in an upright position it will work at a tolerably depth. If the plough does not swim fair, all the effort to keep it in its place draws upon the ploughman, whose labour is thus increased, so much so, that he will not hesitate to affirm that a wheel-plough will draw lighter than a swing-plough that requires such effort. Now, the wheel-plough will not swim fair, unless the various means of adjustment, till he gets the implement to work properly. In the case of the wheel plough, on the other hand, the plough may not be properly adjusted; but it will, nevertheless, keep to its depth, being hindered from going in by the wheels, which thus hinder that inconvenience for the ploughman to which in the other case he was subjected; and he therefore continues working it in that state, and will not alter it, though it should so much dip in as to jerk forward, as if it were running on tiptoe. In the one case the horses are sure of being properly treated, for their comfort depends upon the very same circumstances as that of the workman, while in the other the horses must suffer from the increase in the amount and in the irregularity of the draught, because the comfort of the man is untouched by that increase. With respect to the third argument, its force is acknowledged upon level land, but the very thing which insures uniformity of depth in ploughing level land will, it must be remembered, increase the irregularity of this point in the case of uneven land.

The truth of the first argument in favour of the wheel-plough is acknowledged; but its force is questioned, and I think with justice, when we look at the agricultural character of the districts into which it is admitted, and at that of those where it is not used. It is urged that the implement which performs its work in a passable way, independently of any attention bestowed on it by the workman, is not necessarily on that account to be considered a good one, for this reason, that it tends to produce carelessness in the workman; and, therefore, that the use of the wheel-plough tends to deteriorate the class of agricultural labourers as regards their skill, their industry, and activity. It will not do to say that we can employ boys instead of men with the wheel-plough; many practical men will acknowledge, to a considerable extent, the truth of the remark made by a practical farmer on this subject—that for each boy he had on his farm he was forced to keep a man to look after him.

I perceive, however, that notwithstanding my attempt to state simply the opinion of the two parties, and then judge between them, I have already expressed my own opinions on the subject. It is possible that a spot so level, and workmen so careful and attentive may be obtained, that the wheel-plough may be superior for its cultivation to the swing plough; but for general purposes I certainly believe the swing-plough to be the superior implement. There is one advantage which it has over the wheel-plough, viz, that there are few soils which are not ready for ploughing, and which may not be ploughed by the swing-plough, before the farmer could get on it with the wheel-plough, for the wheel clogs with the wet earth, and thus not only is a continual hindrance to the operation, but by getting an increase, in the shape of earth, to its circumference, the depth at which the implement works is variable

The wheel plough is also objectionable as an invasion of the original simplicity of the implement, and it certainly is so in some of the monstrous forms which it assumes—that, for instance, of the old Berkshire plough. —*M.*

ON MINERAL AND INORGANIC MANURES.

No XXIV.

By Professor Charles Sprengel

The ashes of most herbaceous plants have a greater value than those of wood, being richer in several important salts The analysis of Rape straw will serve as a sample. 100 000 parts of the ashes of Rape straw contain.

2,065	parts	of silica.
2,323	,,	alumina, oxide of iron, oxide of manganese.
16 912	,,	lime.
3,100	,,	magnesia.
18,800	,,	potash, partly combined with silica.
11 210	,,	soda.
13 340	,,	sulphates of lime and potash.
9 900	,,	phosphate of lime.
11,350	,,	chloride of sodium.
11,000	,,	carbonates of lime, potash, and magnesia.
100,000	parts.	

If, therefore, an acre is manured with 1000 lbs. of ashes of Rape straw, the soil will receive 169 lbs. lime, 188 lbs potash, 112 lbs. soda, 133 lbs. sulphuric acid, 99 lbs. phosphoric acid, and 113 lbs. chlorine; and thus it appears that its effects will be greater than those of wood-ashes. The ashes of Rape straw, however, are not the richest in saline matter they are surpassed in that respect by those of Maize and Bean straw, the herbage of Potatoes, and the stems of Tobacco. In order to manure with Rape, it is best to spread the straw thickly over the field, and to set it on fire. The heat will act beneficially on the soil, and kill also all vermin; on which account the result of this operation is always very productive.

Most people believe that the ashes of wood and herbaceous plants improve vegetation only by neutralising the coal (humic acid) contained in the soil, or by bringing the coal of humus to decomposition; this is, however, a mistaken idea. The carbonates of potash, lime, and magnesia, which alone could accomplish this, do not occur in it in that quantity which would enable them to act powerfully: thus, 200 lbs. of potash neutralise only 800 lbs. of humic acid; 200 lbs. of lime no more than 2000 lbs.; and 100 lbs. magnesia only 600 lbs. Consequently, the whole of the carbonic acids contained in 1000 lbs. of ashes would only serve to [illegible] acid; whilst the humic acid of an acre and whilst there

...ashes have been used, contains at times 30,000 lbs. of humic acid. I measured one acre of a sandy soil, containing very much free humic acid, with 2400 lbs. of Scotch ashes, and found—as it could not be expected otherwise—that after the lapse of one, two, and three years, it acted upon chemical tests in the same way as previously; but on, notwithstanding, it produced very fine Oats, Clover, and Potatoes, there is good reason to assume that the ashes nourished the plants, which is the most probable, as we always find them as a component part of crops which have been grown after ashes have been employed. Besides, if it were not the salts of ashes which improve and nourish plants, why should they not be all equally beneficial? We always see that those ashes manure best which are rich in gypsum, phosphate of lime, common salt, and sulphate of potash; and as these salts do not act on the humus of the soil, it is evident that they directly nourish the plants. The silica, alumina, and the oxides of iron and manganese contained in ashes, must not be considered useless; because, though the soil contains a sufficient quantity of these substances, they are not contained in it in such fine particles as in ashes. Silica, especially, may serve the plants as food, the more so, as it is at times combined with potash in such a proportion as to become soluble in water, which also may be the reason why Oats, which are most rich in silica, succeed mostly after ashes.

If ashes are used to the amount of 500 or 600 lbs. per Magdeburg acre, this palpable effect will last only two or three years; as the easily soluble salts are not so much absorbed by the plants as they are extracted by rain. The substances which are hardly soluble in water, like phosphate of lime, carbonate of lime, &c., remain longer in the soil; but this quantity is too small for them to assist vegetation to any great extent. The quantity of ashes used at one time ought not, however, to be too great, else the plants, instead of being improved by the easily soluble salts, will be injured, and a great waste of the salts will take place by rain-water. It is, therefore, always better to use repeated manurings with ashes in small quantities, and this ought to be the general rule with all manures containing many substances easily soluble in water. Clayey soils, however, require always a greater quantity of ashes than sandy soils, and it will not be too much to use 1000 lbs. to 1200 lbs. on one acre of the former, the greater or lesser amount being determined by the proportion of potash they contain. Soils very rich in humus require also much ashes, as in this case a part of the superabundant humic acid is to be neutralised. Fresh ashes will avail such soils chiefly by supplying them with the deficient potash, and it is obvious that those ashes will be preferable which contain most of this alkali. In order to spread ashes well they should be somewhat wetted, and either strewed on the surface in calm weather, or harrowed in with the seed. Generally speaking, in order that the carbonate of potash may not be hurtful to plants, it must be first changed into humate of potash. If, therefore, a soil contains little humic acid, the quantity of ashes used must be very small, and whoever takes no care of this will injure his fields by ashes, rather than improve them.

The manuring with fresh ashes in the neighbourhood of large towns is, comparatively speaking, not very expensive, as we can buy the ashes here at the rate of two-thirds of a dollar per 100 lbs.; if, therefore, even 1000 lbs. should be used per acre, it would only amount to six and two-thirds dollars per acre. We have also constantly to bear in mind, that the constituent parts of the ashes which are absorbed by the plants are soon again returned to the soil in the shape of dung, as only a small portion thereof is retained in the bodies of the cattle. By manuring with ashes the soil is therefore improved for many years to come. It is to be understood that ashes must be kept in a place well protected from rain, else they would soon lose their powerful ingredients.

Experience has shown that vegetable ashes will chiefly improve the growth of leguminous plants, as Lucerne, Clover, Peas, Vetches, &c., which is easily explained by all plants belonging to that family requiring much soda, potash, sulphuric and phosphoric acids, lime and magnesia, and chlorine, for their nourishment, large quantities of these substances being found in their ashes. If wood-ashes are strewed over meadows which produce bad Grasses and Moss, the effect is the appearance, as if by enchantment, of a variety of Vetches and Clovers springing up. On meadows exposed to inundation, ashes cannot be used, any more than upon very wet fields. All plants grown after manuring with wood-ashes are not only much relished by cattle, but are also very nutritious, because they then contain also those mineral substances in great quantity, which are required for the chemical constitution of animal bodies; potash, lime, soda, and magnesia, will also saturate the vegetable acids, and contribute (as has been shown under the head of Marl) towards the forming of much albumen, sugar, and other nutritious substances. Ashes from potash-boilers, bleach-works, and soap-boilers, are used even more than fresh ashes, being much cheaper.

As these extracted ashes will contain but traces of potash, common salt, and other saline matters, easily soluble in water, and will also have lost much of the nitrogen they formerly contained; they will never act so powerfully as fresh wood ashes, on which account large quantities are always to be used—say, two or three tons will not be too much per acre. In this case their effects will not be too much per acre. In this case their effects will not be too much per acre. In this case their effects

cultural Society of England were to publish a Register of the Implements, and Models of the kinds that prizes were awarded to, at their shows, for distribution in the agricultural districts, would be conferring a great benefit on the Country at large.—*Farmer.*—[The Liverpool Ploughs will be very interesting to others exhibited—at least to the curious in such matters.]

Natural Old Land.—It is well known that the soil of an old garden is generally rich for many plants, and that a fresh or new soil is not favourable to them. A list of these plants would more than fill your columns; but I will select three common ones—Strawberries, Turnips, and Potatoes. Every grower of Strawberries must have noted how they delight in new earth. The old garden would produce leaves, but the new soil fruit, remarkable both for quantity and quality. In this case, unfermented vegetable matter may be the cause of plenty. Garden Turnips are never so sweet, or mild, or crisp, as those grown in fields, where, perhaps, they are grown every fourth year with a moderate allowance of manure. In fields too, when Turnips were first grown, they were grown from the same freshness of soil more easily and of better quality than they have been grown since, with all the advantages of modern farming. Twenty years ago I was on a visit to a friend in a part of West Norfolk, where on a good soil Turnips were introduced about 1750. He related to me the experience of his uncle, a strong-headed practical man, who remembered their introduction. I made no note of his recollections, but the substance was this:—That Turnips were grown on this farm without manure, yet with ease and certainty; they were large, and so good in quality, that Scotch bullocks were fattened on them, with Straw and Hay, without any artificial food. The old gentleman used to describe how they were gradually obliged to use manure, and yet that the Turnips lost quality; then they bought Linseed cake, and after a few years introduced Swedes. I once had a garden, in a part of which was a Grass plat some years old, of about ten yards in width. This I had dug over one autumn, for a crop the following spring. Potatoes were planted in April, beginning ten yards to the south of the Grass, the rows running across it as far as ten yards to the north of it. They were a pretty good common kind, and yielded well, but certainly half as much again in the ten yards where the old Grass had been. At the table the difference in quality was most striking; firmness, dryness, flavour, and a peculiar look of the kind, were appreciated in parlour and kitchen. Chemically speaking, what is this Freshness in the soil, and can it be restored by any of the appliances of science? "Common manure will do such effect.—*Rambler.* [So far as we know, your question has never yet been completely answered. Among the reasons why plants flourish better in soil new to them, than in soil on which they have long been cultivated, are, 1st, the extraction and removal from the old soil of those mineral and other substances required as food by the plant, of which it may be supposed the new land has an unexhausted store; and, perhaps, 2d, the accumulation in the old soil of excrementitious matter from the plants grown there, rejected by them as unsuited or injurious to their growth.]

Steeping Seed.—In the early part of this year you promised to make use of Mr. Campbell's steeps, and in due time to give the result of your trial, and your opinion of their merits. The time, I hope, has now arrived, and you are prepared to pronounce your opinion respecting those steeps. Just now are the small farmers who are anxiously waiting your judgment, for the railways have so reduced the supply of manures, and the feeding of cattle, as manufacturers of manure, has been so ruinous of late, that it has become a great question with them what measures to adopt in lieu thereof. If the steeps should be found as effective as the vendor pronounces them to be, they will be most valuable to the poorer farmer, who ought to be an object of your notice. The Ducie's, Miles's, Pusey's, &c. can experiment for themselves. It is said that Professor Johnston has given a recipe for steeps at a much cheaper cost; if so, you will, perhaps, be so kind as to notice them.—*J.M.* [When our Wheat is thrashed out, we shall be able to state the result of the experiment alluded to, and we hope to be able at the same time to publish the experience of our readers on the subject; but our correspondent has only to look at the correspondence on the subject, which has already appeared in late Numbers of the *Gazette*, to ascertain the slight degree of importance to be attached to a single experiment. There is a great deal of contrariety in the accounts we have already received. Let the result be what, within the bounds of probability, it may, these steeps, our correspondent may rest assured, will not render applications of manure unnecessary. Indeed it as seems probable, the vigour of germination and first growth, which the use of the steep probably imparts to the seed, be just as it were an endowment of the young plant with so many additional parts to sustain—so many additional mouths to feed—the use of manure, so far from being rendered unnecessary, will be all the more required. Professor Johnston's suggestion on the subject will be found in No. 29, *Agricultural Gazette.*]

Societies.

HIGHLAND AND AGRICULTURAL SOCIETY.

On one of the days of the late annual meeting of this Society, at Glasgow, a public breakfast took place, under the auspices of some of the leading members of the Agricultural Chemistry Society, in order to have some conversation on agricultural subjects. The question for discussion was—The best Means of making the Practical Farmer acquainted with recent Discoveries in Science, and enabling him to apply them to the Cultivation of his own Farm.—Sheriff Allison explained the object of the meeting. It was of the highest importance that the greatest amount of information regarding the science of agriculture should pervade the community, as upon agriculture, as well as upon manufactures and commerce, depended our national prosperity—national existence. In Great Britain there were twenty millions acres of arable land under the plough; twenty-seven millions in Grass and pasturage; fifteen millions which could be rendered arable; and fifteen millions of mountain pasturage. Supposing, therefore, the twenty millions to be under crop, it appeared from Mr. M'Culloch that the average produce per acre was three and a-half quarters of grain, and by the recent applications of science the average must now be more. Supposing that in addition to the present twenty millions, ten millions more are improved or put under crop, this would be equal to thirty millions acres, and at the average of three and a half quarters per acre, the produce would be one hundred and five millions of quarters of grain or other nutritious aliment. Besides, there are twenty-seven millions of acres of Grass lands, besides the mountain pasture for the rearing of cattle. The average consumption of grain by each individual in Great Britain is estimated as equal to one quarter per annum, so that even independent of the aid of science, the soil of Great Britain is capable of sustaining one hundred millions of inhabitants. And what then would be the state of our manufactures? The value of our home consumption of manufactures was estimated at a hundred and thirty-three millions per annum, and the exports, including the colonial, fifty millions, the foreign alone being thirty-five millions. Now, if the population should increase to a hundred millions, the home consumption of manufactures would increase to four hundred millions a year—eight times the amount of our whole present exports, and twelve times greater than the exports to foreign parts. It was thus demonstrated what our agricultural resources were, and how essentially necessary it was to attend to their development. During the last half century the population had doubled, and attention during that period had been chiefly turned to the development of our manufactures, yet in the 50 years ending in 1836, the amount of grain imported had been gradually diminishing. It seemed to be a law of nature, that as the population increased the power of producing food was also increased. In Poland there were ten cultivators for every one otherwise employed. In the countries west of the Mississippi there were seven cultivators to one otherwise employed; in the United States, an exporting country, three to one; while in Great Britain, by the late census, there was only one cultivator to three otherwise employed. In Great Britain there were ten millions of arable acres never yet ploughed; and, were science properly applied to agriculture, the same results would follow as had followed the application of science to travelling.—Mr. Burnet, of Gadgirth, gave instances of the benefit he had derived from the application of the discoveries of science to agriculture. Land which some time ago was not worth 15*s.* an acre, was now valued at 45*s.*, and produced large crops of excellent Wheat. In some cases where, by the ordinary practice, thirty bushels had been obtained, he had, by the application of ammoniacal manures, raised forty; and by applying saline manures, he had obtained fifty. He had applied gypsum to Clover and Grass, and found his crops doubled; the cattle preferred the Clover, and it remained three years in the ground instead of two years. He had tried gypsum with Turnips, and found it doubled the crop of Aberdeen Yellows, but had little effect on the Swedish; and he found also that gypsum had not the same effects on the crops if the soil had been previously dressed with manure mixed with sulphuric acid.—Mr. Colquhoun, of Killermont, said it is the duty of the landlords to make the experiments—they are somewhat expensive, and often fail at a first trial, and the owner of the soil, who is ultimately to be the gainer, should pay the expense. He had on this point said to an individual, "You seem to make no experiments in your business, and yet you are getting rich, while there is another individual, your neighbour, who makes many experiments, and continues poor." He admitted the fact, but the secret was, that nine out of ten of his neighbour's experiments failed, but when the tenth succeeded, he availed himself of it, and so saved the expense. Science was of the greatest importance in agriculture; but to make it available generally, it must be plainly illustrated and brought to the farmer's hearth. He hoped every one interested in agriculture would endeavour, in his own district, to disseminate information. The information conveyed in the "Quarterly Journal" was not calculated for plain practical farmers: it was too puzzling for them. It was somewhat like going to a doctor, and, on telling the complaint you were troubled with, you should be told the various medicines applicable to the disease, and asked to choose for yourself, instead of taking a prescription to the apothecary to make up for you what you was to drink.—Professor Johnston said, it was undoubted that the application of science to the soil would greatly increase the farmer's profits; but unless the Scottish farmer was put into possession of the knowledge necessary for the proper application of science—not merely a practical knowledge of agriculture, for in that they excelled—they could not profit by it. One great point would be to spread the broad-sheet among the farmers. Wherever he went, he had audiences of 200 or 300 farmers attending him, who paid the utmost attention to him, and seemed to drink in with avidity the information given them. They should, as far as possible, promote the formation of clubs, meetings for lectures, and the circulation of practical papers.

YORKSHIRE AGRICULTURAL SOCIETY.

At the seventh Annual Meeting of this Society, which occurred last week, at Richmond, a very interesting discussion took place, after the Council dinner, upon the subject of drainage. The following account is abridged from the *Durham Advertiser*:—Mr. Lister stated the mode which he pursued:—The substratum of the land upon which I have drained is principally stiff clay, my practice upon which has been this:—The minor drains are cut parallel to each other, and run directly up the hill, the depth of them being from 30 to 36 inches—the latter depth where the clay is very stiff, as I consider the more tenacious the clay the greater ought to be the depth. The main drains run partly at right angles in the hollows, being somewhat deeper than the others. Having a great abundance of stone at hand, I use it in preference to other materials. I break the stones into two sizes, viz., one about the size of road-stone and the other rather larger. In the branch drains I lay a covering of the smaller stones from three to four inches deep, and then cover them with a layer of the larger stones, upon which I put another layer of smaller stones, making altogether a depth of 9 or 10 inches. I then put clay where it can be had, and where not, turf: the clay where used is well beat over the stones; where turf is used, I put part of what has been thrown out of the drain upon the top of the turf and beat it well down—the object of which is to prevent the finer particles of the soil being washed into the drain. I find no difference in effect between covering the stones with clay and turf: the effect of both, in my opinion, is the same, except that where the drain is covered with clay it is much more durable. I would recommend those who use tiles to lay clay over them also where practicable. I am alluding to a clay subsoil; in many parts the clay is very tenacious. I think that the surface-water ought not to run into the drain through the filling in; for then the water must make its way between the active soil and the subsoil, which would be a very imperfect drainage. I differ with Mr. Arkell, who wrote the Prize Essay in the "Royal Agricultural Journal," vol. iv. He says that land lying in ridges is more easily drained, from its lying in a round form, one of these ridges only requiring drains 16 yards apart; whereas if the surface was level it would require the drains to be placed at a distance of six or eight yards from each other. I think this is not the fact; but a level surface would be as easy to drain as a round one. The active soil of my land is from six to eight inches deep; I do not use tiles; and I do not think I could fold sheep upon the Turnips advantageously, except in a favourable season. Not having to lead stones more than half a mile upon the average, I estimate the average expense of my draining per acre 6*l.*, or rather less. It is difficult to say what is the comparative improvement, because my mode of management is so materially altered. I used to have open summer fallows; now I grow Turnips, and carry out the four-course shift. I may observe that land drained is greatly improved by using the subsoil plough. The result of two experiments this year, according to my estimate, is, that my Wheat on the drained and subsoiled land will yield about 40 bushels per acre, while the land of the same character in the adjoining field, which has not been subsoiled, will only yield about 20 bushels per acre.—The Chairman, the Earl of Zetland, said: In offering a few observations upon this subject, I do not wish to throw any doubt upon the statements which we have just heard from Mr. Lister. My object is to state to you the result of the many inquiries that I have made, especially in Scotland, and I will just observe in the outset, that according to the statements which have been made to me, the plan of drainage which Mr. Lister has supported will not succeed so universally—that it is not, in fact, calculated for every kind of soil. My own opinion is certainly in favour of the system of drainage recommended by Mr. Smith, of Deanston. I should recommend that in particular lands a drain at least 24 inches deep should be cut, and that, in filling it up, parties ought not to put the clay immediately above the tile. I have lately returned from a visit to Scotland, and while there I have conversed with the farmers upon this subject, and, amongst other things, I find that one of the plans advocated by Mr. Smith is universally condemned by the agriculturists with whom I have spoken—namely, that of placing the clay immediately above the tile. All those that I have spoken to on the subject—at least all those who have tried this plan in that part of Scotland where I have been—are opposed to it. When I spoke to a farmer in Stirlingshire upon the subject, he replied, "Oh! there is not a farmer in this part of Scotland but would condemn that system." To give you an illustration with respect to this plan of Mr. Smith's:—A tenant of mine in Scotland, in draining part of his farm, turned up some stiff clay. He did not puddle the drain, but filled it up as it came to hand. The clay was of a very strong and tenacious description, and this was placed immediately above the drain, as recommended by Mr. Smith; and if I remember right, the drain was formed 24 inches deep. This land was drained only 10 years ago, and the gentleman to whom I have alluded informed me that this year he was going to take up all these drains, because he found that the water lay upon the top of the ground, and that, too, immediately over the place where the old drains were formed. It could not percolate through the clay, and he had come to the determination of taking up the old drains, and of throwing six inches of loose stones on the top. Where the old drains existed in the clay

able to obtain very indifferent crops, while on those parts which have been properly drained his crops have been most abundant; and he feels assured that, by constructing proper drains in the whole of the land, his crops will be good throughout the farm. There is another fact to which I wish to allude, as I am desirous of throwing as much light upon the subject, and giving as much information as I can, hoping that it may induce gentlemen to try experiments, and thus discover what is really beneficial and of advantage. Last year it was stated that the Duke of Portland had made about 7000 miles of drains in his property, 18 or 20 inches deep, but that he was going to take them up, and sink them deeper. When I saw this statement in the *Mark Lane Express* I was unacquainted with the grounds upon which it was made, and I therefore wrote to the agent of the Duke of Portland for information upon the subject. I received an answer in due course, in which the statement was contradicted. The agent stated that he did not know upon whose authority the assertion was made, but certainly neither on his or the Duke of Portland's. My own opinion upon this subject is different from that of Mr. Smith. I think that drains in clay land cannot be made too shallow, so that the active soil is not disturbed. I believe that drains 18 inches deep—or as shallow as they can be made without disturbing the active soil—are the best.—Mr. Charnock then said—The gentleman who commenced the discussion spoke wholly on stone drainage. Now I apprehend that no stone drainage can be good and efficient unless you have a very considerable fall to commence with. And it ought to be recollected that the greatest portion of the drainage either formed or to be formed in this county is on land having a much flatter surface than is desirable in making drains of the description advocated by Mr. Lister. Perhaps you will permit me to allude to one or two subjects which I consider of primary importance to the attainment of effective and sufficient drainage. With respect to tiles, I think it highly desirable that the agriculturists of this county should be impressed with the desirableness and importance of choosing tiles of a smaller, in preference to those of a larger description. I conceive that there are many objections to the use of large tiles in the majority of cases. In the first place, they are of greater burden and more liable to sink into the clay on which they are placed than small ones; and in the next place they are far more expensive. With reference to the shape and length of a tile, much has been said and many opinions expressed, but I consider that this important question is yet almost unsettled. To-day I inspected some specimens of tiles without any internal foot or sole, which I consider would answer very well in a clayey soil; and in places where this tile can be used I should recommend its adoption, because by doing without a sole you effect a saving of perhaps 25 per cent. per acre. But there are other lands to which this tile would not be applicable. Then, as to the method employed in the filling up drains, I may mention that upon a former occasion I strongly urged the necessity of filling up immediately over the tiles with some porous substance; that is, suppose the drain were to be cut not less than 30 inches deep—but for my own part I should recommend that it generally be cut 36 inches deep—then I think that it is desirable to cover the tile over for 3 or 4 inches with some porous substance, and nothing can be used for this purpose better than loose stones or ling, and then to have the clay trodden down so as to prevent any substance from being washed by the water into the drain. In speaking upon this subject, I will just take this opportunity of stating that I think it is desirable that the water should not filter down through the drain, but that it should percolate from the arch at the bottom. And, from my own observations, I am led to think that, in general, the great bulk of the water, particularly in wet soils, finds its way into the drain from the bottom. There are many matters connected with this subject, which must remain in great doubt until actual experiment shall have set the matter at rest, and I will take the liberty of suggesting whether it is not desirable that the Council of the Society should institute some experiments for the purpose of eliciting, as far practicable, information upon the various points connected with practical and successful drainage.—Mr. Thompson, of Kirby, observed, with respect to the shape of tiles, that most people were now in favour of pipe-tiles; but he would mention a case that occurred within his own knowledge, in order to show that they were not always to be depended upon. It would be, perhaps, known that, in the earlier days of draining, the common brick was the only tile used, and this was made to form a pipe about an inch and a half in diameter. About two years ago, he had occasion to open an old drain formed of bricks in this manner: the drain had almost ceased to be of any use, and he was anxious to discover the reason of the imperfect drainage of the land where this old method had been adopted. On examining them he found that the bore or hole of the drain was as nearly as possible filled with the oxide of iron. He ought to have observed that the land was nearly though not quite level, and at first when the drain was formed, it would be found sufficient to carry off the water, but the ground being impregnated with iron, the oxide had collected, and in the end, as he had stated, nearly filled up the aperture of the drain. This was the result of the experiment which he had made with reference to small pipe-drains, and he apprehended that in all cases of a similar description, it would not be a safe plan to use them. He had also opened another pipe-drain which had been formed for a period of upwards of 20 years. The width of this drain was very considerable—being no less than six inches, and upon opening it he found that it had become stopped up in consequence of the growth of a certain description of weed which is sometimes found in drains.—Mr. Turner, agent to the Earl of Zetland, said: There is a very important fact which I think all parties ought to take into their consideration when about to drain land, and that is with respect to the after treatment of the soil. Suppose that it is intended to lay the land into permanent pasture, and that it is never intended to let a plough enter it, then I state with confidence that the nearer you place your drains to the top the better. I do not mean with reference to shallowness; but supposing that you sink, say 30 inches, then I would fill the drain nearly to the top with stones. While, however, I recommend this plan with respect to pasture land, I should think that I was displaying the utmost ignorance did I pursue the same system on an arable farm. In this country we are as yet but little acquainted with the advantages likely to result from the use of the subsoil plough, and all persons who can lay aside their prejudices and use this plough, will take care to lay their drains in such a manner as not to interfere with the use of such a valuable implement. There is another circumstance which I wish to mention to agriculturists generally, as it seems to have been lost sight of by the champions of the respective systems of drainage. These gentlemen seem to have forgotten that we have a natural drain-maker at work, namely, the earth-worm, and that in time, however tenacious or strong the clay may be, the soil must become more or less porous through its exertions. I think, therefore, that it is utterly impossible for you permanently to prevent the water from entering the drain. Some gentlemen have stated, and I have seen the theory advocated by certain of the public journals, that the water really passes down to the top of the drain; and there are others who contend that it enters from the bottom, but for my own part I am of opinion that it enters the drain at the sides. In forming a well, you find the water comes in at the bottom; but the cases are not parallel, because parties when they bore for a well merely sink to a spring. With regard to the best and cheapest material to be employed in making drains, until the time arrives when tiles may be obtained for 20*s.* per 1000, I think it is the duty of every agriculturist to drain with stone where practicable.—Mr. Etheridge stated that it was impossible to lay down a law suitable to every case. Surely it must be admitted that there ought to be some difference made between a surface spring and an under spring. The clayey soil of Sussex ought to be treated differently from the soil of Kent, or from that of Northumberland. With respect to the description of tile to be adopted, he considered the pipe-tile upon the whole to be disadvantageous. It was well known that on all clayey soils they were sure to meet with sand or other porous substances in digging for drains, and let the person employed in digging be ever so clever or practical a man, he would be unable to remove this matter entirely away. The consequence was that when the drain was filled up, this matter would in all probability be pressed into the joints of the pipe, which would soon become partially filled or disturbed, and, owing to its small diameter, it would in a short time become useless. He had not heard any complaints with respect to double tiles, which fitted into each other so as to prevent any matter from entering at the joints. The tiles would cost generally 14*s.* or 15*s.* a thousand, but the price would depend in a great degree upon the locality. The first item would be the price of the clay, the next the labour, and the next the quality and the distance the coal would have to be led. He could show that where the common double tile is used the expense ranged from 10*s.* to 15*s.* a thousand.—Mr. Salvin then said, by delaying to drain the land great injury was inflicted upon the farmer. The cost of manuring an acre of land with artificial manure amounted to more than 5*l.* per acre, and should this manure be put on the ground before it was drained, the consequence would be that in many cases it would hardly ever reach the seed. To show the increased productiveness of land after drainage, he stated that while in Kent he was informed by an agriculturist, that upon part of his farm the average produce formerly was not more than 24 bshls. of Wheat per acre; whereas, after it had been drained, the same land produced 40 bushels.—Mr. Crompton then spoke on the subject of liquid manure. Within the last four years he had constructed four tanks for the purpose of collecting the liquid manure from his fold-yard. The first was a very small one; and here he would impress upon any gentleman who intended to construct a tank not to follow his example, but to make it large in the first instance. He should recommend him to make it about half the size of the area of his fold-yard, and then it would contain all the liquid manure that ran from the yard. Two of these tanks were erected in stiff clayey soil, and two in porous land. Those in the clayey land held water immediately, while those in the gravelly soil had to be cemented before they became sufficiently tight. He filled these tanks three times a year, but he had found by experience, that if they had been sufficiently large, so that he could empty them at one season, the beneficial effects would have been far greater. Were he enabled to water the whole of his Grass with this manure in the spring the effect would be truly astonishing; he was convinced that if applied in the proportion of 30 cubic yards to an acre of Grass, it would be found to produce as heavy, if not heavier, crops than any quantity of other manure that could be applied. Indeed, the crops were so heavy that were they to be increased they would prove injurious to themselves. He had tested the quality and quantity of the Grass produced on the land watered by this manure with that of Grass grown on land manured with another description, and the result was decidedly in favour of liquid manure. The Earl of Zetland had published, in the Transactions of the Society, the result of an experiment which he had made with respect to the application of farm-yard manure to Grass land. The quantity of Grass grown on a certain portion of land so manured, together with its weight, was there stated. Now, when he read this statement he determined to make a comparison between the produce of this land and an equal portion which he caused to be watered with liquid manure. The Grass was dry, and the result was that he found the quantity of Grass produced on the land watered by the liquid manure was nearly double to that which had been reported by his Lordship. In this experiment he watered the land at the rate of 25 cubic yards to the acre, though generally speaking 30 cubic yards were the quantity which he used, and with this he was convinced that he obtained as good crops as any agriculturist would wish. He was only able to manure 12 acres in this manner, but then he ought to observe that he cut the whole of this twice in the year, and each time he obtained a good crop. Two years ago he applied a quantity of this manure—at the rate of 25 cubic yards an acre—to a field of seeds, and the result was, that the crop was certainly one-third larger than any other in the country which he heard of. That was the only experiment which he had made with this manure on light soil, the rest having been laid on clayey land. Mr. Crompton then stated that when he began to use this manure he pumped it out of the tank with a copper pump. In less than 18 months, however, the corrosive matter in the manure completely destroyed the pump. He then got one made of cast-iron, but in less than two years this was rendered useless. He then ordered his joiner to make him a wooden one, and this had been found to answer the purpose most satisfactorily. It had been now in use five years, and did not exhibit any symptoms of decay.

Lecture in the Town-Hall.—At two o'clock on Tuesday, in the Town-Hall, Dr. Robinson, of London, author of "Chemistry for the Use of the Agriculturist," &c., delivered a lecture on The Utility of a Knowledge of Chemistry to the Agriculturist, as a Means of saving him from the Frauds practised in the Adulteration of Artificial Manures. After some general observations, in the course of which he showed the impossibility of ascertaining, without the aid of chemistry, the genuineness of artificial manures, he explained the nature and properties of guano, which is the deposit of fowls that feed on fish. He illustrated the manner in which the purity of this and other valuable manures of a highly fertilising character might be tested. The first experiments related to the blue stone vitriol, or sulphate of copper, which, though not used as a fertiliser, is known to be of considerable importance to the agriculturists in many districts, being used in the preparation of grain for seed. He said that, some six years ago, whilst at Rochester, he was waited upon by some farmers to test something which was offered by the agent of a London drysalter as blue vitriol, at 3½*d.* a pound, the usual price being 7*d.* or 8*d.* a pound. At the first sight he could not tell whether the article was blue vitriol or not, but by applying a common chemical test—namely, by dissolving a portion of real blue vitriol in a glass, and a portion of what was called blue vitriol in another glass, and adding to each a little ammonia (or hartshorn)—he at once detected the imposition, the solution of the genuine article remaining perfectly blue, while the spurious one turned black, and he thereby discovered that what was offered was green vitriol, or sulphate of iron. In order to render the latter less easy of detection, it had been powdered, and he cautioned agriculturists, as a matter of prudence and a check to imposition, never to purchase anything they might require in a ground state, if it could otherwise be obtained. Turning to the subject of guano, Dr. R. said, when pure it contained two highly fertilising properties in great abundance, namely, phosphate and urate of ammonia, as well as very fine bone-dust; and he showed by an experiment, that when genuine, it would dissolve in diluted muriatic acid or spirit of salt. After some remarks on nitrate of soda, a valuable stimulant for many kinds of Grasses, he tested it by applying a quantity to red-hot coal. The pure was shown by a beautiful bright blaze, unaccompanied by any noise; whilst, when adulterated by common salt, the presence of the salt was ascertained from the dulness of the blaze and a continued crackling. This test did not apply when nitrate of soda was adulterated with common washing soda. It then required that it should be dissolved in water, and the presence of the washing soda would be indicated by effervescence on the application of oil of vitriol; while salt was readily dissolved again in ammonia. The concluding experiment related to gypsum or sulphate of lime, and it proved that pure gypsum would not effervesce on the addition of oil of vitriol, but when common chalk, with which it is often adulterated, was present, it was indicated by rapid effervescence. All the experiments were of the most simple character, and were all performed by means of two or three common tumbler glasses.

Miscellaneous.

Experiments on Irrigation.—The first field experimented upon in irrigation contains about one-and-a-half acre imperial measure, which was lying a few years ago in a state little better than useless. From its proximity to the farm-steading, it had for many years been used as a park for the calves, which were reared upon the farm for a few weeks, until they were weaned and put to other pasture. But, as a proof of its great sterility,

when we entered to the farm at Whitsunday, 1839, we put two calves into it in the month of June, and were obliged to take them out two or three weeks afterwards, as it did not grow as much Grass as to support them. Its herbage was of the coarsest description, and although in a sheltered situation, much of the ground was unewarded, and stunted heather was beginning to show itself upon some of the driest parts, while a few straggling rushes were a sickly appearance upon those parts which were saturated with wet. In January, 1840, we turned it over with the plough, and found the soil to be much inclined to Moss, especially in the lower part of the park. It appeared as if it had been burned at some former period, as the soil was partly mixed with ashes. In the lower part of the park the subsoil is a stiff gravelly clay, while across the middle it becomes hard and stony, and is only covered with a few inches of surface; from this part a large quantity of mineral water flowed, and left a brown ochrey sediment on the surface; nearer the top the soil is a dark-coloured earth about six inches deep, and the subsoil a fine clay. We sowed it with Oats in the spring, and, excepting a small space at the upper end of the park, it was a very poor crop. We furrow-drained it in autumn, and planted it with Potatoes in the spring following, with farm-yard manure at the rate of about 25 cubic yards per acre; the crop was middling good, being about 28 bolls, or 7 tons per acre. We then ploughed it into ridges about 18 feet broad, to answer the declivity. In the following spring we spread upon it the small quantity of about 10 bolls, or 60 bushels, of lime shells, per acre, and harrowed them in with the Oats and Grass seeds. Perennial Rye-grass of excellent quality, which had been cut after the nineteenth year, and a few pounds of red and white Clover, were the only seeds sown; the crop of Oats was middling good, being about 7 bolls, or 42 bushels, per acre; but the sward of Grass in autumn was far from luxuriant. We applied the water to it in the month of November, which was done in the following manner:—A small rill, which has its source from a few drains at a little distance, had trickled by the steading for a great length of time, without being used for any other purpose than to afford drink to cattle, for which purpose, at times, from the smallness of the run, it was scarcely sufficient. During wet weather, however, in the winter season, it sometimes swelled to a considerable size, and as it then brought the washings of the farm-road along with it, from a distance of about 300 yards, we thought it might be turned to some useful purpose in irrigation. We were in the habit of collecting all the urine from the offices into a reservoir, and carting it to the fields; but there was at times a considerable loss of that valuable liquid from the dunghill, which, when fully saturated, ran over. If, therefore, we could by any means raise the water of the rill to a sufficient height to come in contact with the refuse liquid of the dunghill, and form a small reservoir, it would then in wet weather catch all the rich washings of the premises, and conduct them over the park in irrigating rills. We managed to effect this, and we have not been disappointed. When we got the water raised to a sufficient height, we formed a main conducting feeder along the head of the ridges, and made small feeders from it to conduct the water occasionally into each ridge. The supply of water was small, and to prevent waste, we laid the bottom of the feeders with clay, which we got puddled at the clay-mill in the vicinity. The water was generally not more than sufficient for one ridge at a time, so we commenced at one side of the field, and regularly watered it ridge by ridge. We usually allowed the water to flow only about two days over a ridge, when we turned it off into another. We spread it over the ridges by damming the cuts with pieces of slate or stone. When we got once over the field, we commenced again at the other side, and continued to do so during the winter. That part of the park which lay at the greatest distance from the water was apt to get a less supply than the rest; but, fortunately, a few drains emptied themselves into a ditch which ran along the side of the park, and of this we took advantage, by raising the water in it to a sufficient height, where it had ample declivity to run along a cut made across the ridges; and we found that, from the feeding qualities of this water, and partly from a little of the more fertilising liquid soaking into it from the flooder above, that it had a most wonderful effect in promoting fertility. Indeed the effects of the irrigation were visible in a few days after this contrivance was applied. Whenever the weather was fresh during the winter, the Grass assumed a green appearance, and nothing could exceed the luxuriance of its growth when the spring set in. We allowed a few ewes and lambs to pasture on it the first two weeks of April, which kept it back a little, but commenced cutting the Grass about the beginning of June, and cut and consumed it green by horses and cows for nearly two months. Before it was all cut it was much too ripe, and some beginning to rot at the roots; but as the cattle continued to relish it, and it was so conveniently placed, we were loth to make any of it into Hay. We, however, measured and won a portion of it to ascertain its weight per acre, and found it to be 402 stones, of 22 lbs. to the stone per imperial acre. This portion was cut about the middle of the field, and might be reckoned a fair average sample. It was cut July 26, and weighed August 16. The second crop was excellent, being exceedingly heavy where the first crop was earliest cut. We commenced cutting it the second time on the 20th of August, and we cut a beautiful third crop from a considerable part of it till the frost came on the 13th of October, when its growth was completely checked, and we then allowed the cows to eat up the foggage. When cutting the second and third crops, the sward was so close, that the swathe might almost have been rolled up like a fleece of wool. Thus we have reason to believe that, by the continued application of the water, small as its allowance is, the ground may still, in future years, increase in fertility, and, of course, prove a valuable acquisition to the farm. It is now worth as many pounds a-year as it was before worth shillings, and the means which have been used to improve it have not been expensive, and any future charge that may be incurred to maintain and increase its fertility, will cost nearly nothing, seeing that the application of no fertilising ingredient is required but what heretofore ran to waste. The second portion of irrigation consists of about three imperial roods, which lie in a steep acclivity on the banks of a river. It is too steep to be brought under cultivation by the plough, and, being a dry gravelly soil, the want of sufficient moisture in summer seldom failed to render it almost useless. Having, two years ago, furrow-drained the field immediately above it, we led the main-drain in a direction where we could catch another small supply of water that came from the surrounding fields. This was nearly all that was required; we had merely to make a small cut as a flooder along the top of the bank, and another across about half way down, when we let a small supply of water into each, and the steep declivity rendered it an easy matter to spread it over the surface. We kept the water upon it throughout the whole winter, and during summer, until a week or two before commencing to cut the Grass. When the supply of water was very small, we let it run a few days in one flooder, and then in the other; but we found that it did no damage when it was allowed to run continually upon the same part. The first year the irrigation was applied, being 1842, it had no great effect, and the Grass which was cut from it was foul, and not highly relished by the cattle; but in autumn a beautiful sward appeared; and in the present year, 1843, nothing could exceed the luxuriance of its growth, the water being still applied in the same manner. The Grasses were much finer in quality than in the preceding year, and the cattle devoured it greedily. We measured and won a part of it to ascertain the weight, and found it to be the extraordinary weight of 440 stones, of 22 lbs. to the stone, per imperial acre; the Hay was cut on the 7th of August, and weighed on the 28th of the same month. Thus another small portion of land has been brought from comparative barrenness into a state of great fertility, by means both simple and cheap, as a very small amount of labour and attention have been required, and for which, certainly, we have been most amply repaid.—*Mr. Wilson, of Penicuik, in the Transactions of the Highland Society.*

On Rolling Wheat.—Agriculturists in general allow that a friable soil is favourable to the growth of Wheat; and they even recommend a harrowing in spring, to loosen the soil and promote the action of the air and the sun. In an experiment I have tried, I set out on a principle entirely opposite, founded on a practical fact. We like to trample the sprouting Wheat in October and November by flocks of sheep, for the purpose of pressing the soil. The treading of these sheep causes every trace of vegetation to disappear: yet the Wheat fields so treated look the finest in spring, and yield the best crops. This trampling by sheep must not be confounded with folding, to enrich the soil, for the sheep, in treading a field, drop very little dung, which would only fertilise the spots where it fell; but the fields thus trodden exhibit a vegetation uniformly vigorous. In the month of October, 1842, I passed my heavy roller, above 4 feet long and 4 feet diameter, and weighing about 3 tons, once over a field of about 5½ acres. The Wheat had come up, and the rolling was even and complete. In this operation I had in view to condense the soil that it might not absorb moisture, and that no water should lodge upon it, because this, in freezing, would, of necessity, injure the young plants. I also thought that compressing the soil, which promised to be particularly favourable to Wheat, would retain moisture in fine weather more effectually, and that the roots, fixed more firmly in the ground, would push up more vigorous shoots. My anticipations were realised beyond expectation; the field was uniformly covered with plants, which shot up early in the spring, and continued to flourish until harvest. All the neighbouring farmers observed it with astonishment. The 5½ acres of Wheat compressed by the roller consisted of light sandy soil, mixed with a little clay, not well adapted to Wheat, which prefers strong soil; and it had been cropped the year before partly with Wheat and partly with Oats. I had, therefore, transgressed the ordinary rules of rotation by sowing Wheat again; but I hoped to compensate this disadvantage by manuring the land. From these 5½ acres I reaped 213 bushels of Wheat, weighing about 5½ tons, and about 12 tons of straw. This is a very satisfactory produce on a light soil of moderate quality. By mistake, my whole field was rolled, and therefore I could not ascertain the difference between portions that were rolled and those that were not; but, judging from the crops of my neighbours, I must believe that the rolling of my field augmented the produce one-fourth. The compressed state of the field continued until harvest; and, from the first, I was struck with its compactness. I remarked that a weed, which grows only on highways much frequented, was collected on my field, whilst other weeds were very rare, notwithstanding the frequent rains of 1843. However, I found no difficulty in working it, and I sowed it with Turnip and Rape, some parts of which were rolled immediately after the seed was put in. I had some portions watered with solutions of salts of ammonia, and I have rolled some Wheat, leaving parts of the field untouched. Next year I shall be able to speak more positively of the effects of heavy rolling. I make a successful use of my high-way roller on my meadows in early spring. A single rolling is sufficient to produce a hard, smooth surface, conducive to the growth of herbage, and easy to be closely mown.—*M. Schattenmann, in the "Annales de Chimie et de Physique," Ayrshire Agriculturist.*

Sale of Guano at Liverpool.—A cargo of guano brought by the ship Hamilton, Ross, from Ichaboe, was offered for sale on Friday, by Mr. Alexander Allen, broker, at the Sale-room in Oldhall-street. The quantity announced was 350 tons, but only 250 tons were offered, the difference having been disposed of by private contract. The article was said to be the best ever imported, and the analysis showed that it was of superior quality. It was divided into four lots of five tons each, and twenty-three lots of ten tons each. The biddings commenced for the first lot at 5*l.* per ton, and rose slowly by half-crowns to 5*l.* 10*s.*, at which it was knocked down, and the purchaser took the next lot, making ten tons altogether. The third and fourth lots were put up, and sold at the same price. The first lot of ten tons was offered at the same rate, the broker stating that no more would be sold at that price, but there were no higher biddings, and it was withdrawn at 6*l.* Twenty tons were all that was sold. The attendance was rather numerous, but there was little or no competition.

Notices to Correspondents.

ALLOTMENTS.—*S. L. S.*—We quite agree with you, and will have the subject attended to fully.

ARE RABBITS GAME?—Rabbits are not game within the Game Act, 1 & 2 Will. IV. c. 32. We have not seen the opinion in *Bell's Life in London* referred to, and therefore do not know the precise point upon which it was given. The opinion given in a former Number is correct. We understood the question of our then correspondent to be—Whether a tenant could use a gun to kill rabbits on his land without taking out a game certificate, and we referred him to the exception in Schedule L. of 52 Geo. III. c. 93, to show that he could. *W.*

BARLEY AND RICE.—*T. C.* asks for information on the nutritive qualities of Rice and Barley-meal, and also on the relative nutrition of the bran and flour of Wheat. Have any of our readers experiments on these matters in the fattening of cattle to report?

CLOVER DODDER.—*G. Kirk.*—It has probably a foreign origin, being introduced into this country with Clover seed. Mr. Babington, of St. John's College, Cambridge, requested some time since that farmers would send him specimens of this weed, and of the seed, with information as to where the seed was obtained.

DRAINING LEVEL.—*Constant Reader.*—A very excellent level was exhibited at Southampton, by Mr. Bailey Denton, as you will see in our report of the Exhibition. We do not know Mr. Webster's.

GYPSUM.—*A. H.*—We will endeavour to get the title of the book you refer to for you, next week.

NAMES OF PLANTS.—*J. Y.*—The small sweet-scented plant from South America is Melilotus parviflora. It has been cultivated in Botanic Gardens, but not as an agricultural plant that we ever heard of.

PROFESSOR JOHNSTON'S STEEP.—*A Correspondent* was last week erroneously referred to No. 29 of the *Agricultural Gazette* on this subject; it should have been to No. 19, where he will see the following substances recommended as a steep for Corn and Beans:—Phosphate of soda, sulphate of magnesia, nitrate of potash, common salt, sulphate of ammonia—1 lb. of each, in 10 gallons of water, to steep 300 lbs. of seed. To be dried with gypsum or quicklime.

RATS.—*Proteus.*—Mr. Meyer's Rat Poison is continually advertised in our columns.

STALL-FEEDING.—*A Teifiside Subscriber.*—A field of six or eight acres should answer your purpose, one third of it to each of the three roots, Parsnips, Carrots, and Mangold Wurzel. Give your cows 10 or 12 lbs. of hay each day, and as many Carrots and Parsnips as they will eat besides; which will probably be from 80 to 100 lbs. Mangold Wurzel should not be given till March or April.

SULPHATE OF IRON.—*C. B.*—See the advertisement over the Leader of the *Agricultural Gazette* last week.

WOOD-ASHES.—*Peter Drill.*—See Sprengel's Paper on this subject in this Number of the *Gazette*. You may put on 15 or 20 cwt. per acre. You need not deprive the ashes of causticity if you apply them on fallow land a fortnight or so before putting other manure in the ground. Plough them in immediately. We do not think the addition of sulphuric acid is advisable.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, Aug. 19.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 10	to	4s 2	Best Downs & Half-breds	3s 10	to	4s 0
Best Short Horns	3 8		3 10	Best Long-wools	3 6		3 10
Second quality Beasts	3 0		3 6	Hows and second quality	3 4		3 8
Calves	3 4		4 4	Lambs	3 8		4 4
Pigs	3 4		4 4				

Beasts, 2726; Sheep and Lambs, 24,320; Calves, 138; Pigs, 295.

We have again a short supply of Beasts, and a brisk trade. Although we cannot make any alteration in our tabular statement from last week, yet there is a slight advance on the best qualities; everything is readily disposed of; the second quality is also more in demand than of late, but does not make any more money; a large proportion of the supply is of very middling quality. There are a larger number of Sheep and Lambs than last week, but the demand is also increased, and the advance realised on Friday is fully supported to-day—namely, a little more than 4*s* for the best Downs, and rather over 3*s* 10*d* for the best Longwools, but not a quotable advance. Lamb-trade is still worse; the season for this article is nearly closed. Veal is a rather worse trade, very few of the choicest quality making 4*s* 4*d*—indeed many very good ones are sold at 4*s*. Pork is much more in request at an advanced price.

FRIDAY, Aug. 23.

We have a fair supply of Beasts to-day, but most of them of middling quality; the trade is about the same as on Monday: the best Scots, &c., are readily sold at from 3*s* 10*d* to 4*s* 2*d*, and Shorts-horns about 3*s* 10*d*—in some instances a little over; a good clearance is effected. We have not quite so many Sheep and Lambs, but the trade is very dull, and it is very difficult to support Monday's prices; the best Downs make no more than 4*s*, and Longwools nothing over 3*s* 10*d*, Ewes and second quality 3*s* 8*d* to 3*s* 6*d*. Veal-trade is still heavier, and the best Calves cannot be quoted at more than 4*s*. Lamb-trade is very bad; very few make 4*s* 4*d*. Pork remains steady.

Beasts, 780; Sheep and Lambs, 9760; Calves, 200; Pigs, 290.

41, West Smithfield.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, Aug. 22.

Prime Upland Hay	100s	to 110s	Clover	100s	to 130s	Straw	34s to 36s
Inferior ,,	85	95	,, New	——	——		
New Hay ,,	90	90				Joint Coupon, Salesman.	

CUMBERLAND MARKET, Aug. 22.

Superior Old Hay	100s	to 110s	Superior Clover	120s	to 130s		
Inferior ,,	90	95	Inferior ,,	100	110	Straw 32s to 33s	
New Hay	90	100	New Clover	110	120		
						Joshua Bates, May Salesman.	

WHITECHAPEL, Aug. 23.

Fine Old Hay	85s	to 105s	Old Clover	120s	130s	Straw	32s to 33s
New Hay	90	95	New Clover	110	120		

COVENT GARDEN, Aug. 21.—In consequence of the steady state of the weather the market has been well supplied during the week with both fruits and vegetables, and generally speaking little alteration has taken place in the prices of most articles. Trade is, however, far from being brisk. Pine-apples of good quality are plentiful, and Grapes are also quite sufficient for the demand. Peaches and Nectarines are abundantly supplied, as are also Plums of every kind; Greengages are exceedingly plentiful; Apricots are becoming scarcer. Of Apples and Pears there is abundance; but there is little demand for them. Melons are good and plentiful; Morello Cherries are selling at very nearly the same prices as last week. Gooseberries are nearly over; a few, however, may still be seen in the market. Currants are scarce. Filberts are becoming plentiful and are in consequence getting cheaper. Tomatoes are supplied, but not in large quantity; they are very good in quality. Among Vegetables, Cauliflowers are good and plentiful, as are also Cabbages. French Beans are sufficient for the demand, and a few Windsor Beans are also in the market. Onions are plentiful. Peas continue to get less abundant. Celery is tolerably good; it has not altered in price since our last report. We observed a few samples of Cape Broccoli in the market. Among Cut Flowers were Stephanotus floribundus, Euphorbia splendens, Bignonia venusta, Ceanothus azureus, Camellias, Heaths, Sweet Peas, Verbenas, Fuchsias, Scarlet Pelargoniums, Roses, Pæonies and Carnations.

FRUITS.

Pine Apple, per lb., 4s to 6s	Cherries, Wall, per lb., 1s 6d to 2s 6d

VEGETABLES.

Cabbages, per dozen, 6d to 1s 3d	Spinach, per sieve, 1s 6d to 2s 6d
Cauliflowers, per doz., 2s to 3s	Leeks, per bun., 2d to 3d
Broccoli, per bundle, 1s to 1s 6d	Chilis, per 100, 2s to 4s
Sorrel, per hf.-sieve, 6d to 9d	Garlic, per lb., 4d to 6d
Artichokes, per doz., 1s to 2s	Onions, per bunch, 2d to 3d
French Beans, p.hf.-sv., 1s 6d to 2s	— large, per bushel, 1s to 2s
Potatoes, New, per cwt., 2s to 3s	Shallots, per lb., 4d to 6d
New Turnips, per doz. bch., 4s 6d to 5s 6d	Tomatoes, per half-sieve, 4s to 7s
Peas, per bushel sieve, 2s 6d to 3s	Lettuce, per score, 6d to 1s 6d
Beans, per bush. sieve, 1s 6d to 2s 6d	Celery, per bunch, 1s to 1s 6d
Red Beet, per doz., 1s to 2s	Mushrooms, per pottle, 6d to 1s
Carrots, per doz. bchs., 3s 6d to 6s 6d	Small Salads, per punnet, 2d to 3d
Basil, per bunch, 2d to 4d	Watercresses, p. 12 sm. bun. 2d to 4d
Horse Radish, per bundle, 2s to 3s	Parsley, per doz. bunches, 1s to 2s
Savory, per bunch, 2d to 3d	Tarragon, Green, per bunch, 2d to 3d
Cucumbers, Frame, each, 3d to 9d	Green Mint, per bunch, 2d to 3d
— Ridge, doz., 2d to 3s 6d	Marjoram, per bunch, 2d to 3d
Vegetable Marrow, per doz., 4d to 1s	Chervil, per punnet, 2d to 3d

HOPS, FRIDAY, Aug. 23.

THE Market is very firm, and Sussex Hops are sought after at 2s to 4s advance on last week's prices. Duty, 165,000l.

FARNHAM & SMITH, Hop-Factors.

MARK-LANE, MONDAY, Aug. 19.

SINCE Thursday the weather has become fine, and the accounts from the country are more favourable than could be expected—indeed it is the general opinion that much injury has not been sustained from the rain, and harvest is progressing rapidly. On Monday last there was some degree of life in the trade, which was increased on Wednesday, owing to the bad weather continuing. Foreign Wheat on Friday was sold at 2s. to 3s. over Monday's prices. There were about 1000 qrs. of New Wheat up for to-day's Market, the quality of which was fine, and condition generally good; it sold from 52s. to 58s. per qr. The trade for Old and Foreign was dull at about 1s. above the rates of this day se'nnight.—Barley meets a good demand, and fully maintains our quotations.—Beans are 2s. dearer.—White Peas unaltered in value, but Maple and Grey 1s. higher.—Oats are a difficult sale, and barely maintain the prices of last week.

BRITISH, PER IMPERIAL QUARTER.

Foreign	—	112	28080	18542	—	28080	—	1566	3589

FRIDAY, Aug. 23.

The arrivals of English Wheat since Monday have been moderate, and prices remain nominally the same as on that day; the fineness of the weather, and disinclination on the part of the holders of Foreign to submit to any reduction in its value, causes the transactions to be of a limited character. The quantity of Wheat cleared in during the week at the 18s. duty was about 36,000 qrs.—Barley and Beans continue to meet a good inquiry, and the terms of Monday are in some instances rather exceeded.—In Peas there is no alteration.—The Oat trade is very inactive, and late rates scarcely maintained.

A variety of upwards of 50 tea and coffee services may be seen in the show-rooms, where may be selected every article of silver requisite for the side-board or plate chest. Pamphlets of prices, illustrated with sketches of the various articles, gratis, and forwarded, postage-free, to any part of the kingdom.—A. B. SAVORY and SONS, 14, Cornhill, London, opposite the Bank of England.

Bound in cloth, price 5s. 6d.

JOE MILLER'S JEST-BOOK. A Reprint from the first and genuine Edition, such omissions and alterations only having been made as were required by the greater delicacy observed in modern conversation; but, that the volume might have some substance, and be a good table or travelling book, copious additions have been made from other old volumes of Facetiæ.

Extract from the Preface.

"Another strange circumstance connected with this work is, that everybody presumes that he himself and everybody else are perfectly familiar with its contents . . . and yet, if the reader will ask his acquaintance, it will appear that not one in five hundred ever set eyes on a copy. It is in consequence of like questions that this edition is published."

London: WHITTAKER and Co.

Now ready, price 4s. 6d.,

RURAL CHEMISTRY.

Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry, at the Royal Institution.

&c. &c. &c.

Extracts from the Introduction.—

"A knowledge of the chemical composition of soils and the various substances employed as manures enables us to comprehend the mode in which the latter act; and a knowledge of the nature of those substances which plants require, points out the best and most economical methods of restoring to the soil, by manures, those substances which plants remove from it."

"If the farmer knows what it is that gives the fertilizing powers to manure, and is aware of the nature of those substances, he will soon learn the best method of preserving and using them: he will then understand how to make the most of the various sources of manure at his disposal, and he will be enabled readily to save much, that, for the want of such knowledge, would otherwise be lost."

PRINTED FOR

TAYLOR AND WALTON,

BOOKSELLERS AND PUBLISHERS TO UNIVERSITY COLLEGE

UPPER GOWER-STREET

DARLEY'S SCIENTIFIC LIBRARY

FOR

SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

It is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the public at large. To youth of either sex at public and private schools; to persons whose education has been neglected, or whose attention has not been directed in early life to such studies; and to Artists and Mechanics these little works will be particularly suited The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible, the demonstrations of propositions are made plain for the mind and brief for the memory; and the Elements of each Science are reduced not only to their simplest but to their shortest form

I

A NEW EDITION (being the fifth) *is now ready*,

A SYSTEM OF POPULAR GEOMETRY;

Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles

BY GEORGE DARLEY, A.B.

Price 4s 6d, cloth

II

NEW EDITION (Just published),

COMPANION TO THE POPULAR GEOMETRY;

In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts.

BY GEORGE DARLEY, A.B.

Price 4s 6d, cloth.

III

THIRD EDITION,

A SYSTEM OF POPULAR ALGEBRA;

WITH

A Section on PROPORTIONS and PROGRESSIONS.

BY GEORGE DARLEY, A.B.

Price 4s 6d

"For students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge, article "Mechanics."*

IV

SECOND EDITION,

A SYSTEM OF POPULAR TRIGONOMETRY,

Both Plane and Spherical.

With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.

BY GEORGE DARLEY, A.B.

Price 3s 6d., cloth.

V.

FAMILIAR ASTRONOMY.

BY GEORGE DARLEY, A.B.

WITH ENGRAVINGS—12mo, 5s, cloth lettered.

"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, not less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr Darley."—*Sun.*

Just published, the Fourteenth Edition, price 3s. 6d., free by post, 4s 6d.,

THE SILENT FRIEND on NERVOUS DEBILITY, CONSTITUTIONAL WEAKNESS, &c. By R. and L. Perry and Co., Surgeons, London. Published by the Authors, and sold at their residence, also by Strange, 21, Paternoster row; Noble, 169, Chancery lane; Crosker, 5, Milford-lane, Strand; Ward, 168, Strand (opposite Exeter Hall); Gordon, 146, Leadenhall st; Parkins, Compton-st, Soho; Wilcox, 238, Oxford-st (two doors from Argyll st), London The Cordial Balm of Syriacum is a stimulant and renovator in all Spasmodic complaints Nervous Debility, Indigestion, Asthma, and Consumption, are gradually and imperceptibly removed by its use, and the whole system restored to a healthy state of organization Sold in bottles, price 11s and 22s Perry's Purifying Specific Pills have long been used as the most certain remedy for Scorbutic Complaints of every description, Eruptions of the Skin, Pimples on the Face, and other disagreeable affections, the result of an impure state of the blood. These Pills are perfectly free from mercury and other deleterious drugs and may be taken with safety without interference with or loss of time from business, and can be relied upon in every instance. Sold in boxes, at 2s. 9d., 4s. 6d, and 11s, by all Medicine Venders

Messrs Perry and Co may be consulted daily at their residence, 19, Berners street, Oxford-street, from 11 till 2, and from 5 till 8 On Sunday, from 10 till 12.

HEATING BUILDINGS by HOT WATER.—A PRACTICAL TREATISE on WARMING BUILDINGS by HOT WATER, on Ventilation, and the various Methods of Distributing Artificial Heat, and their Effects on Animal and Vegetable Physiology To which are added, an Inquiry into the Laws of Radiant and Conducted Heat, the Chemical Constitution of Coal, and the Combustion of Smoke By CHARLES HOOD, F R S, F R A S, &c Just published, Second Edition, greatly enlarged, with numerous woodcuts, &c, 8vo, price 16s 6d cloth

WHITTAKER and Co, Ave Maria lane, London; and to be had of any bookseller

NEW EDITION OF COL HAWKER ON SHOOTING.

Published this day, 8vo, 21s cloth, the NINTH EDITION of INSTRUCTIONS to YOUNG SPORTSMEN, in all that relates to GUNS and SHOOTING. By Lieut Col P HAWKER Corrected, enlarged, and improved, with Eighty-five Plates and Woodcuts, by Adlard and Branston, from Drawings by C Varley, Dickes, &c

"The very best book we have on the subject"—*Blackwood.*

"Colonel Hawker expounds the whole *rationale* of shooting with clearness fulness, and vivacity"—*Edinb Rev*

London LONGMAN BROWN, GREEN, and LONGMANS

MR HOARE'S NEW WORK ON THE VINE

This day is Published, 12mo, 5s cloth,

A DESCRIPTIVE ACCOUNT OF A NEW METHOD OF PLANTING AND MANAGING THE ROOTS OF GRAPE VINES By CLEMENT HOARE, Author of "A Treatise on the Cultivation of the Grape Vine on Open Walls"—London LONGMAN, BROWN, GREEN, & LONGMANS

TO NAVAL OFFICERS AND OTHER GENTLEMEN.

LECTURES at the ROYAL POLYTECHNIC INSTITUTION, by JOHN RYAN, M D L L D, &c A new course of instruction on "the Properties of Steam as applied to Naval Purposes," will commence on Monday next, 26th inst.

E J LONGBOTTOM, Secretary.

N B Practical instruction in Chemistry daily.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c Manufactured by DOULTON and WATTS, LAMBETH POTTERY, High street, Lambeth, London.

D and W, from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it impermeable, and gives it a sharpness and surface which no changes of temperature can impair

D and W are enabled to offer the Terra Cotta at a considerable reduction in price, and Drawings and Designs will be forwarded Gratis, on application —Architectural work executed.

DRESS AND FROCK COATS.—Superfine Cloth Dress Coats 30s to 35s, Extra Quality, 40s to 50s; Frock Coats with Silk facing, 35s, to 42s, with Silk Velvet Collar & Silk facing, 50s; Waterproof Chesterfield, Codrington and Travelling Coats, 12s, 15s, and 21s; Waistcoats, 5s 6d to 8s 6d, rich Satin, Silk and Cassimere, 8s 6d to 12s 6d; Trowsers, 6s 6d to 10s 6d, Doeskin and Kerseymere, 12s 6d to 21s, Shooting Jackets, 10s 6d, Boys and Youths' Cloth, Hussar Suits, 21s to 30s A Suit of Superfine Black Cloth, 3l, Extra Quality, 3l 10s. to 4l At FISHER & Co's, Tailors, 31, King William street, City, ten doors from London-bridge

PATENT COMPOSITE CANDLES.—These Candles burn without snuffing more brilliantly than the best Wax, and are cheaper in proportion to the light given than the commonest Tallow Candles The Patentees respectfully beg all purchasers to ask in the shops simply for "PRICE'S PATENT CANDLES,' as many imitators have adopted the term "Composite." They are sold by most of the respectable Dealers throughout the Kingdom, and are supplied wholesale to the Trade by EDWARD PRICE and Co, Belmont, Vauxhall, and by PALMER and Co, Sutton street, Clerkenwell, London

TO LADIES

ROWLAND'S KALYDOR.—This Royally Patronised and universally adopted Specific is a balmy odoriferous, creamy Liquid composed chiefly of extracts from the most rare Flowers and Herbs of an Eastern Clime Its discovery was no less singular (by a Lady of rank), than its effects have been felicitous, during the last thirty years It is the mildest and most efficacious preparation ever known for dispelling Tan, Pimples Freckles, Discolorations and other Disfigurements of the Skin The radiant bloom it imparts to the Cheek and the softness and delicacy it induces on the Hands, Arms and Neck, render it indispensable to every Toilet

Gentlemen will find it peculiarly grateful after shaving, in allaying irritation of the skin and in rendering it soft and smooth

Price 4s 6d and 8s 6d per Bottle, duty included.

CAUTION —The great demand for this article excites the cupidity of *unprincipled Shopkeepers*, who vend the most *spurious* trash as the 'GENUINE KALYDOR'—whereas the genuine article is prepared solely by A ROWLAND and SON, and the amalgamation of its *costly exotic* materials renders abortive any attempt to discover its component parts—thus proving the imposition of all other articles bearing the title of "KALYDOR" The genuine article has the words "ROWLAND'S KALYDOR" on the Wrapper.

*** All others are FRAUDULENT COUNTERFEITS!!!

Printed by WILLIAM BRADBURY, of No 4, York-place, Stoke Newington, and FREDERICK MULLETT EVANS, of No 7, Church row, Stoke Newington both in the county of Middlesex, Printers, at their Office in Lombard-street, in the precincts of Whitefriars, in the City of London; and published by them at the Office, No 4, Chronicle-street, in the parish of St. Paul's, Covent-Garden, in the said county, where all Advertisements and Communications are to be addressed to the Editor.—Saturday Aug 24, 1844.

PRIZES OPEN TO ALL ENGLAND will be awarded by the THANET FLORICULTURAL SOCIETY, on Thursday, the 12th September.

Best 24 Dahlias, 4l.; Second-best ditto, 2l.

Place of Exhibition, Ranelagh Gardens, St. Peter's, near Margate. No entrance money demanded.

FUCHSIA "CONSTELLATION."

WILLIAM MILLER begs respectfully to inform his Friends who have kindly favoured him with their orders for the above splendid Fuchsia, that his stock only consists of a few plants, and he is therefore obliged to defer sending it out this year.

N.B.—Wanted a quantity of seedling Beplasrum fruticosum. Providence Nursery, Ramsgate, Aug. 27, 1844.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs Warner and Warner, Cornhill, London, after the 7th September

ACHIMENES PICTA

W. J. EPPS begs to announce that he has the finest and largest Stock of this valuable plant, which he can supply strong plants of at 5s. to 7s 6d; also the new and splendid blue Buddlea Lindleyana 5s, Drymonia punctata 5s, Aristolochia Gigas 5s., Clerodendrum Wallichii (a distinct and beautiful variety) 5s. Strong plants of nearly all the new Fuchsias sent out this year, 15s. per dozen.—Bower Nursery, Maidstone, Aug. 28th, 1844.

EXHIBITION OF LILIUM LANCIFOLIUM

HENRY GROOM, Clapham Rise, near London (removed from Walworth), by Appointment FLORIST TO HER MAJESTY, begs to inform the Nobility, Gentry, and Amateurs that his extensive assortment of this most beautiful Lily, including the rare and splendid variety "speciosum" which is held in such high estimation by the Japanese, is now in flower, and will continue in perfection about a fortnight, and may be viewed every day, Sundays excepted. Admittance Gratis.

JOHN SLATER, FLORIST, Cheetham Hill, near Manchester, respectfully calls the attention of the Floricultural Public to his large and select collection of the following Florists' Flowers.—TULIPS, AURICULAS, POLYANTHUSES, CARNATIONS, and PICOTEES; catalogues of which may be had on prepaid application. 12 plants of named Auriculas, of different varieties, for 20s, package included.

TO CALCEOLARIA GROWERS

THE present being a good time to sow CALCEOLARIA SEED, the Advertiser begs to offer a few packets of his splendid New Spotted kinds, saved with great care, with printed directions to raise the young plants, at 5s. per packet. —J. STANDISH, Nurseryman, Bagshot.

INGA PULCHERRIMA. (Figured in "Paxton's Magazine of Botany" for August, 1844.)—Fine Plants of this extremely elegant and beautiful Exotic, with most of the other new and rare Plants of the season, may be obtained of the undersigned, at the following low prices:—

Inga pulcherrima, 7s. 6d.

CEDRUS DEODARA, 3 ft. to 3 ft 6 in., 10s 6d. per plant.

N.B. All Orders above £2 are delivered carriage free to London or Hull, or plants added to compensate for the same.

Great Yarmouth Nursery, August 20, 1844.

TO THE LOVERS OF PANSIES.

S. WIDNALL, Grantchester Nursery, Cambridge, begs to inform his friends and the public that he has with great care selected his Superior PANSY SEED, warranted to be all new of the present year, and which he can with confidence recommend. This being a favourable season for sowing, it will be advantageous to those who wish to ornament their gardens with this beautiful flower at a very cheap rate, as packets containing sufficient seed, with careful cultivation, to grow 300 plants and upwards may be had postage free at 2s. 6d per packet, or three packets for 5s, upon receiving a post-office order.

T. AND J. BACKHOUSE, NURSERY & SEEDSMEN, York, beg to offer to the notice of the Public their following fine SEEDLING PANSIES —

YORKSHIRE ECLIPSE.—"No. 1 is a large flower, of good form, white ground, blue purple upper petals, and broad margin of the same round the lower petals, the petals meet well above the eye, a good flower." 2s. 6d.

BEAUTY OF HOLDGATE.—"No. 2 is your best flower; the eye large and intensely dark, ground light buff, belting purple, upper petals the same; a brilliant and striking flower." 3s. 6d (See *Gardeners' Chronicle*, p. 280, for 1844.)

EARL OF ZETLAND is a flower of excellent form, yellow ground, bronzy crimson upper petals, with broad belting of the same round the lower petals, which meets well above the eye, a distinct and very constant show flower 3s. 6d.

Strong plants are now ready for sending out, postage free when three or more plants are taken. A remittance required from unknown correspondents

TRUE HIGHLAND PINE.

JAMES GRIGOR, NURSERYMAN, Norwich, begs to call the attention of the Land Proprietors of England to this very desirable variety of Pinus sylvestris, which has been raised from seeds collected on the mountains of Strathspey, and of which he has strong plants ready to be sent out. For introducing this tree Messrs. GRIGOR, of Forres and Elgin, were awarded several premiums by the Highland and Agricultural Society of Scotland, and in that part of the country this Pine is rapidly superseding the common soft-wooded variety. For all economical purposes its chief merit consists in the hardness and durability of its wood; hence it is much sought after at present for railway sleepers. Picturially considered, or as a landscape ornament, it rivals even the Cedar of Lebanon. Sir Walter Scott describes it as assuming much of "the bold and contorted figure of the Oak," and in the last No. of the *Quarterly Review* it is recommended as a fit tree to be planted in churchyards and cemeteries.

Strong plants in pots, such as rabbits and hares will not destroy . . . . . 6d. each.
Ditto, not in pots, 18 inches high . . . 30s. per 1000.
Ditto " 15 " . . . 20s. "
Ditto " 1 foot high . . . 15s. "
Ditto " 3 years old . . . 10s. "

J. G would recommend all who require them to furnish themselves immediately with these Pines, and to plant them forthwith Spring planting is exceedingly hazardous; and when followed by such a season as was experienced during the commencement of the present summer, the young trees are sure to be killed.

Cedrus Deodara raised in the open ground, being the strongest plants yet offered in England, 10s. each. Araucaria imbricata, Pinus excelsa, Laricio, Austriaca, &c. &c. on reasonable terms

PINE PLANTS.—Persons in want of the above have an opportunity of choosing from a particularly strong and healthy stock, warranted clean, at moderate prices. Apply personally or per post to W. DAVIS, Green-street, Marlboro'-road, Chelsea.

SPLENDID NEW SEEDLING CINERARIAS.—Strong Plants fit for autumn and winter flowering, saved from the very choicest sorts, selected from between 6000 and 8000 seedlings, comprising every shade of deep rich purple, dark and light blue, &c, 9s per doz. Packets of Seed, selected as above, 2s 6d each. Also, strong plants of the following fine flavoured STRAWBERRIES.—

	per 100		per 100
Myatt's British Queen	6s. 6d.	Green Flesh Pine, small fruit, fine flavour	3s. 6d.
" Eliza	5 0		
Emperor, early variety from Keen's Seedling	3 0	Elton Pine	3 6
		Keen's Seedling	3 6

Applications, including post office orders, will be immediately and carefully executed.—Direct to MICHAEL BRAWEN, Sen., Nursery, London road, Cambridge.

TO THE LOVERS AND AMATEURS OF ROSES.

WOODLANDS NURSERY, MARESFIELD, near UCKFIELD, SUSSEX.

WM. WOOD AND SON have the pleasure of announcing to their Friends that their newly-arranged CATALOGUE of ROSES is now ready, and may be had GRATIS on application. It will be found to contain all the newest and best varieties in cultivation.

W. W and Son take this opportunity of informing Amateurs that their extensive collection of autumnal flowering Roses are now in splendid bloom. Admittance daily, Gratis (Sundays excepted).—Woodlands, August 27.

MR. LYNE'S NEW SEEDLING GERANIUMS.

WILLIAM E. RENDLE has much pleasure in offering to the Nobility, Amateurs, and Trade the following new varieties of GERANIUMS raised by P. E. Lyne, Esq, the entire stock of which he has succeeded in obtaining.

	each	s.	d.
Lyne's Princess Alice	each	1	1
Lyne's White Perfection	"	1	1
Lyne's Imogene	"	1	1
Lyne's King of Saxony	"	1	1
Lyne's Redworth	"	1	1
Lyne's Confidence	"	1	1
Lyne's Sappho	"	1	1

The whole set as above for six guineas. The usual discount to the Trade

"Princess Alice" has received two seedling prizes in London. "White Perfection," first prize at Torquay, and the Gold Medal at Plymouth. "Imogene" is described in the *Chronicle*, June 24th, 1843. They all possess most desirable properties, and can be highly recommended as being first rate flowers.

W. E. R. has been induced to offer the above at prices considerably lower than usually obtained for such valuable varieties, in hopes thereby to meet with a more extensive demand. Descriptions can be obtained on application.

Orders will be executed in strict precedence. Plants will be delivered in October next. References or remittances required from unknown correspondents. Plants will be added to compensate for carriage.—Union Road Nursery, Plymouth, Aug. 28

NEW AND RARE PLANTS.

W. JACKSON AND CO., NURSERYMEN, SEEDSMEN, and FLORISTS, have now the pleasure to offer the following Novelties —

Cineraria Celestial, No. 1. . . . . 5s. each.
" Fairy, No. 2. . . . . 5s. "

See Dr. LINDLEY'S opinion in the *Gardeners' Chronicle*, of April 6, page 216, under the letters, C. L. N. "Seedling No. 1, a bright blue. The flowers of this variety are rather small, but they are very abundant, and bright and beautiful in colour. No 2, pure white centre, with the termination of the petals of a delicate azure blue. This is also an abundant bloomer with well-formed flowers, lively in appearance, and forms a distinct and desirable variety." Discount to the Trade on the above when six plants of each are ordered.

Boronia ledifolia, 5s.; Choreozema triangularis, 5s; Epiphyllum, Conway's Giant, 2s.6d. to 5s., large; Kennedianum, 2s.6d.; Gastrolobium spinosum, 5s.; Gompholobium polymorphum luteum, 5s, Hydrangea Japonica, 2s. 6d.; Mirbelia speciosa, (Luddiges') 5s, Oxylobium acutum, 5s.; Pimelea spectabilis, 2s 6d., Thunbergia chrysops, 7s. 6d.; Veronica speciosa, 2s 6d. to 7s. 6d. each, large.

W. JACKSON and Co. beg to state that their 60 beautiful Seedling Calceolarias, selected from upwards of 2000, will be sent out early next Spring, a descriptive Catalogue of which will be printed. Railway communication to all parts of the kingdom. A reference from unknown correspondents is respectfully solicited.—Cross Lanes Nursery, Neadle, Yorkshire.

EARLIEST STRAWBERRY in CULTIVATION. —Strong Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 30s. per 100. As an Early Strawberry, it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the "British Queen," "Deptford Pine," "Prince Albert," and all the leading kinds. To be had of Messrs. WARNER & WARNER, Seedsmen, 26, Cornhill, London.

AURICULA SEED from Stage Flowers, to be had in Packets at 2s 6d., of W. J. NUTTING, Seedsman, 46, Cheapside, London.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of Seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. In Tin, 1l. 10s. each; or with Copper Box and Tube, 1l. 15s. each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. COTTAM and HALLEN, 2, Wimsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers in the United Kingdom; or from the Inventor, by letter, to his address, inclosing a Post-office order for the amount.—RICHARD SMITH, Upper Hall, near Droitwich, Worcestershire.

SUPERB HYACINTHS, ANEMONES, TULIPS, &c., just received from the most celebrated growers in Holland, and will be delivered free of all expenses at the railways, packet offices, or in any part of London, at the very moderate prices annexed.

Messrs. SUTTON and SONS, Reading, Berks, respectfully present the above as a select list of the sorts most worthy of cultivation, and recommend early application, while they possess fine roots of every variety.

N.B.—Parcels delivered free to any part of London, and properly packed for conveyance to any distance.

THE NEW SUPERB SEEDLING PICOTEE,
"BURROUGHES'S DUKE OF NEWCASTLE."

YOUELL & CO. have much pleasure in announcing they will send out for the first time the above splendid light-edged purple Picotee, raised by the Rev. J. Burroughes. It is guaranteed to surpass any Purple Picotee that has yet been raised. Without commenting further upon its superiority, Y. and Co. beg to refer to a report in a late No. of the *Gardeners' Chronicle*, as follows:—

"The *Duke of Newcastle* is a flower of first-rate properties; it is a light-edged purple; the petals are large, and of good form and substance; even on the edge; the colour unbroken; the pod good, and with less disposition to bar than is common" It obtained the first prize, as the best seedling, at the Norfolk and Norwich Horticultural Exhibition. Price 21*s* per pair, and will be sent out the latter part of next month. The stock being limited, to prevent disappointment early orders are respectfully requested. Y. & Co. will also be enabled to supply at the same time the following superb Picotees, raised by the same gentleman, all possessing first-rate properties, and having been exhibited and obtained first class prizes at several of the metropolitan Exhibitions of the present year. They are as follows:—

		s.	d.
Burroughes's Mrs. Bonyon, Red Picotee		7*s.*	6*d.*
,,	Lady Alice Peel, Rose Picotee	7	6
,,	Miss Jane, Purple Picotee	7	6
,,	Miss Bevan, Red Picotee	7	6
,,	Enchantress, Scarlet Picotee	5	0

CARNATIONS AND PICOTEES.

Y. and Co.'s collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit. The plants are remarkably strong and healthy, and will be ready for sending out to any part of the United Kingdom and the Continent the latter part of September, at the following prices:—

				£	s.	d.
12 pairs extra fine and very superior first-class Show Flowers				2	10	0

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	Orange Tubs, Flower Boxes, &c.
Garden Edging	

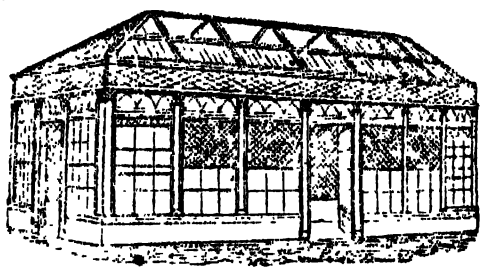
EDWARD BUCK will be happy to answer any inquiries, either personally or by post.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Plantes, Propagating Houses, &c., by which atmospheric heat as well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS and Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane square.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Aug. 30, 1844.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Aug. 30, 1844:—

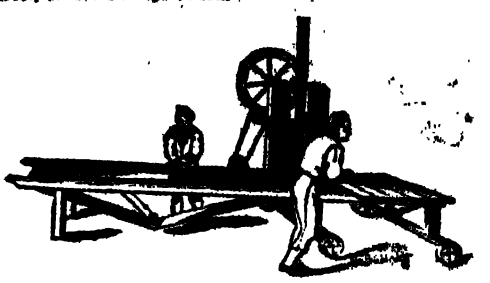
WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

TO FLORISTS AND ADMIRERS OF FLOWERS.

BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

This preparation is peculiarly adapted for the development of Flowers furnishing them with the materials (in a soluble form) out of which they weave their delicate tissues and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing-room.—Price 1*s.* 9*d.* per quart Bottle, and may be had of WM. JACKSON, late Geo. Butler, 93, Cheapside, corner of King-street, and most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas-st., Stamford-st., Blackfriars-rd.

BY HER MAJESTY'S ROYAL LETTERS PATENT.



PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 24 inches wide, at 1*d.* per foot, super. A discount to the trade. TEES. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

GYPSUM, &c.—Burn Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.; also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.
Synopsis of Prices, and mode of use, on application.
MARK FOTHERGILL, 46, Upper Thames-street.

HATCHER'S BENNENDEN TILE-MACHINE. Manufactured and Sold only by COTTAM and HALLEN, Engineers, Agricultural Implement Makers, &c., 2, Winsley-street, Oxford-street, London.

This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With this amount of labour, the product of a day of 10 hours is as follows, viz.:—

1 inch diameter of Tile,	11,000	1½ inches diameter of Tile,	5,000
1½ ,, ,,	8,000	2½ ,, ,,	3,200

The Machine is movable down the drying-sheds, so that it requires no extra boys to carry the Tiles, nor are shelves required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Cranbrook, Kent. No charge made for Patent dues or licence. The purchase of the Machine includes free use of it.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water-courses. In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. BAILEY DENTON has arranged with an eminent London Mathematical Instrument Maker to make them in any number required. Price 30*s.*

This Level is as accurate as a spirit-level, and so simple, that the workman unable to read can use it with facility. When closed it forms a 5 feet staff.

Orders addressed to Mr. DENTON, Land Agent, 9, Gray's Inn-square, London; or to Mr. CHARNOCK, Wakefield, Yorkshire, will insure a perfect instrument.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon-Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Boxes and Lights complete, from 1*l.* 8*s.* Garden-Lights made and glazed from 1*s.* per foot, at JAS. WATTS' Sash Manufactory, Claremont-place, Old Kent-road. *** Reference given.

MESSRS. PROTHEROE AND MORRIS have received instructions from T. and C. LOCKHART not to proceed with the Sale as advertised in the *Gardeners' Chronicle* of the 10th and 17th inst.

T. AND C. LOCKHART, FLORISTS and SEEDSMEN, 156, Cheapside, London, having dissolved Partnership with Mr. ANDREW DUNCAN, beg to inform their Customers and the public generally that they will carry on their business as usual at the above address. Their Catalogue of BULBS and FLOWER-ROOTS for the present season has just been published and will be forwarded, post-free, on application.

NURSERY STOCK, KING'S ROAD, CHELSEA.

MR. KIRKE respectfully begs to announce that he has received instructions to Sell by Auction, on the premises, (late The American Nursery) King's Road, Chelsea, on Wednesday, September 11th, at 11 for 12 o'clock, by order of the proprietor, the ground being required for other purposes, the Valuable Collection of CACTUSES, GERANIUMS, CAMELLIAS, ORANGE, LEMON, and CITRON TREES; ALOES, FUCHSIAS, YUCCAS, CHRYSANTHEMUMS, AZALEAS, and SUCCULENT PLANTS; the whole in pots, and arranged in small and large lots to suit the convenience of purchasers; GREENHOUSES, &c. &c.—May be viewed two days prior to sale. Catalogues had on the premises; of Messrs. DIXON and Co., Covent Garden; of Messrs. T. and C. LOCKHART, Seedsmen and Florists, Cheapside, City; and at the Offices of the Auctioneer, 29, Brompton-row, Brompton.

TO BE LET, on Lease of 10, 15, or 20 years, from Michaelmas next, the RECTORY FARM, LITTLE GRANSDEN, containing 400 acres, of which about 250 acres are old and 150 new land; all under-drained.—Apply to the Rev. F. NORRIS, Granaden Rectory, near Caxton.

FARMS TO BE LET ON LEASE.

TO BE LET ON LEASE, HOLMSTEAD FARM, consisting of 239 Acres of Excellent Arable, Pasture, Meadow, and Wood Land, free of Corn Tithes, with a good Farm-house, convenient Out-buildings, and walled-in Cattle-yards well supplied with water. Also HULKS FARM, comprising 185 Acres, with a Capital Newly-erected House and Farm-buildings. There are about 60 acres of Woodland, which may be had with this if required.

The above Farms are situated in the parishes of Cuckfield and Bolney, Sussex; and are about 15 miles from Brighton, skirted by the London turnpike-roads, and 2½ miles from the Haywards-heath Railway station. Possession may be had at Michaelmas.

For further particulars, apply to A.C., 13, Charles-street, Middlesex Hospital, London; or at Holmstead.

STOCK FARM.

TO BE LET, at Michaelmas next, a very compact Farm, with convenient Buildings, consisting of 445 acres of Arable, 98 Pasture, and 188 of Downs Land, in a good state of cultivation, and part of it may be entered upon immediately. —For further particulars apply to Mr. SAMUEL DRUCE, Eynsham, near Oxford.

TO GARDENERS, NURSERYMEN, AND OTHERS.

TO BE LET, with immediate possession, within 20 miles of London, a small NURSERY, and PUBLIC-HOUSE doing a good business. The Nursery is well stocked with choicest American Shrubs, Fruit, and other Trees; is situated within a few minutes' walk of a railway station. Every particular can be procured by application to Mr. KNIGHT, 6, Great Russell-street, Covent Garden; and Mr. MASS, Nurseryman, Wandsworth Common. No person without capital need apply.

BRIGHTON FLORAL and HORTICULTURAL SOCIETY.—The Exhibition of the above Society will be held at the Town Hall, on Wednesday, Sept. 18, 1844, when, in addition to the premiums offered by the Society, there will be two Prizes given for Grapes—one a handsome Silver Dessert Knife and Fork and Spoon, in case, for the best dish of Grapes of any colour, not exceeding 4 lbs. weight; the other a Prize of two large Silver Table spoons, for the best dish of Black Grapes, not exceeding 4 lbs. weight. The above is open to all England. Entrance, 2s. 6d. each. Persons who intend to exhibit are requested to send their names and address on or before the 16th Sept. to the Secretary, Mr. R. COLLINGS, Duke-street, Brighton.

The Gardeners' Chronicle.

SATURDAY, AUGUST 31, 1844.

MEETINGS FOR THE FOLLOWING WEEK.

Tuesday,	Sept. 3	Horticultural	3 P.M.
Friday,	Sept. 6	Botanical	3 P.M.

WE resume the consideration of HYBRIDISING. Some of its actual results have already been pointed out (p. 459); others will suggest themselves to any one acquainted with gardening. Let us now consider what further may be hoped for.

What further? Why, we have only stepped over the border, and the whole field of hybridising lies widely spread before us; its boundaries are lost in the horizon, and we shall find them still receding as we advance.

In directing attention to this part of the subject, we do not here propose to include the plants cultivated by the farmer, but to confine ourselves strictly to garden plants. What agricultural applications hybridising may have will be found hereafter in the other department of our Journal.

The ends which it is hoped to gain by all operations directed towards improving the races of plants are many.—To increase the size of flowers, To improve their colour, To approximate their form to some assumed standard of perfection, To enlarge the foliage, as in esculents, To render tender plants hardy, To make barren races fertile, To improve flavour, by changing acidity or austerity into sugary matter, To exchange early for late varieties, are all results that have been gained by hybridising, and which, therefore, may be gained again. We propose to consider each of these points separately.

How far the *size of flowers* may be thus increased can be judged of from the Rose, the Dahlia, the Fuchsia, Pansy, Pelargonium, and Cactus. All these plants are, in their wild state, small-flowered; cultivation alone has increased them greatly, but crossing has rapidly carried it further. By inoculating the common Heartsease with the large-flowered Pansy of the Altai mountains, a degree of vigour was infused into the former which we could not have hoped to obtain by any other means. In other cases, as in that of the Dahlia, by observing the first symptoms of a tendency to enlarge in the natural seedlings, and then crossing the best of them, the tendency has received an immediate impulse, which has by degrees brought about the enormous flowers we are all familiar with. The flowers of Cereus speciosissimus were inoculated with the pollen of Cereus grandiflorus by Messrs. Davis and Co., of Wavertree; and the *immediate* result was a seedling from C. speciosissimus, whose flowers were 10 inches in diameter.

In prosecuting this branch of improvement, care should be taken to select the finest possible flowers on both the father's and mother's side, and to render them unnaturally large by destroying all their neighbours. The plants, too, should be in the most robust health; for we may be sure that no point of constitutional vigour is to be neglected in the parents when a general and permanent increase of it is desired in their offspring. It is moreover conformable to the experience of the late Mr. Andrew Knight, that even the plumpest seeds are more likely to bring a fine seedling than the weaker.

Among the commoner plants to which attention might be drawn under this head, are not merely those which, like the Verbena, the Petunia, and the Cactus, are already in the florists' hands, but others, that have yet gained little attention. Take the Clematis, for example: our wild Traveller's Joy is unknown in gardens, although it has a fine foliage, and a great vigour of growth. Why not cross it with C. florida, or Viticella, or even Flammula? Clematis Viticella is a bad grower, but has beautiful blossoms; it, too, may certainly be improved by some of the finer species. Then, again, the Minores Clematis, with its fine speckled blossoms, is tender, and flowers very late; what would be the effect of an intermixture of it and C. montana, which is so hardy, and flowers so early? What a noble plant, too, is C. azurea to work with! It must not, however, be crossed with any of the red species, for reasons that will be explained hereafter. Can anything be more worthy of attention than this charming genus, which nobody seems to have thought about? To those whose leisure enables them to prosecute such an inquiry we may state that in all probability the species of Clematis will cross most readily in the following order, viz.—1. *C. flammula, vitalba* and *cylindrica*; 2. *C. florida, azurea, viticella, balearica*, and *montana*; but there is no apparent reason why they should not all also intermix, in skilful and patient hands.

Another important race of Climbers are the Honeysuckles. The flowers of our common Honeysuckle are little more than an inch long; but those of the beautiful Tuscan species (Caprifolium etruscum) are twice as large, and in the Caprifolium longiflorum of China the blossoms are full three inches in length. Here are the best opportunities for an improvement of one of our most favourite plants.

Nor do we regard the case of the common Jasmine as hopeless. It is true that it does not produce its berries with us; but if it were kept under glass, and artificially fertilised, it probably would do so. Why not intermix it with the beautiful species from the Azores. It would, in all probability, give its hardiness to that plant and receive in return a finer foliage and more abundant bloom; or, at least, it would hardly refuse to mingle with the Catalonian Jasmine, which is so like it, and then our cottages might be covered with plants as beautiful as those of Barcelona and Italy.

The Laurustinus is another plant entirely neglected by growers of new plants, and yet there is no reason why its flowers should not become as large as those of the Guelders Rose—itself an artificial production. What would be the effect of inoculating the finest of the varieties of the Viburnum opulus, the parent of the Guelders Rose, with the Laurustinus? Either, we should expect, an evergreen Snowball-tree, or a Snowball Laurustinus; or, at least, a considerable enlargement of the flowers of the latter; or, may be, the issue would be a hardier Laurustinus than we had before. But that is beside the present question, which we confine to an enlargement of the blossom.

The double Japan and Chinese Cherries (Cerasus japonica and sinensis), among the finest of our spring shrubs, would be infinitely improved if the size of the common Cherry could be communicated to them; and there is no apparent reason against it. And in like manner the little Dwarf Almond (Amygdalus nana), not now much grown, though a very pretty bush, might, and most likely would, be readily improved by a mixture with the common Almond, or still better with that magnificent variety called in the gardens Amygdalus macrocarpa.

If we turn from shrubs to herbaceous plants, there is the same abundance of materials on which to work. Why not attempt to mix Tropæolum brachyceras or canariense with the common Nasturtium? or the beautiful Hypericum Coris with H. androsæmum, or H. erectum with calycinum? or the annual Larkspurs with Delphinium grandiflorum? or the whole race of Dianthus, including the Indian Pinks and Sweet Williams, with the Cloves and Carnations? or the gay Sea Lavenders with such plants as Statice arborea and Dickinsonii? or, finally, our wild Buttercups with the gaudy Ranunculus of the florists?

In all these suggestions there is nothing in the least contrary to probability; the plants that are adverted to are all of common occurrence, and easy for any one to operate upon—indeed they have been selected for that reason; and they offer an abundant reward to skill and patience.

The other points above alluded to must be considered hereafter.

DISEASES OF PLANTS.—No. II. *See p.* 131, 1844.

[MOSSES, LICHENS, &c.]

BEFORE we enter on the consideration of those morbid appearances which are produced in plants by the agency of Fungi, we proposed to consider how far other cryptogamic species are injurious. In the few cases in which they are so, it is not by the production of any particular disease, but by simply overrunning the leaves and branches, and thus blocking up the stomata, preventing the proper influence of light, keeping up an unnatural moisture, or affording a nidus for the development or preservation of injurious insects. Several species of Mosses and Marchantia, Vaucheria terrestris, and Microcoleus, &c., are very noxious weeds, especially in the case of small and tender plants preserved in frames, and the delicate seedlings of Ferns are frequently destroyed by Palmella botryoides and others of the smaller terrestrial algæ; and they are in some measure the more annoying to the cultivator, because they are extremely difficult of extirpation. If the gardener complains sometimes that his lawns are spoiled by many of the more common Mosses, though in certain situations they add very much to the beauty of his close-shaven sward, the farmer with greater reason laments over his pastures overrun with Moss and Lichen till they are all but useless.

In these cases, however, they are injurious simply by encroaching on the ground which was destined for more useful tenants, and however hurtful occasionally, they cannot be regarded in the light of diseases. In damp situations I have seen trees much infested with the common green Chlorococcus, an Alga of the most simple construction, not only the trunk and branches being covered as with a green wash, but the leaves themselves becoming entirely coated with it, at once to the great disfigurement and injury of the plants thus invested. But the injury produced does not arise from the rootlets penetrating into the tissues and nourishing the parasites at their expense, with the juices intended for the support of the mother plant, but merely as a coat of any other coloured wash, by clogging up the pores and hindering a due assimilation of the sap. In hot countries the leaves of many phœnogamous plants, and the fronds of the more rigid Ferns, are frequently overrun with various species of Moss and Jungermannia, but it is principally the older leaves, whose functions are nearly past, that are thus infested; and it is possible that in some cases they may even be of use in retaining a certain quantity of moisture about them. In these cases, again, there is not the slightest penetration of the rootlets into the tissues of the plant on which they grow. It is scarcely necessary to mention that the Mosses which so often and to such an extent adorn the trunks of our trees, grow upon them, merely because the cracks in the bark and the mouldering surface itself affords a fit soil for the germination of their spores and the support of the full-grown plant. Lichens vegetate on the hardest bodies, as granite, quartz, and glass, and not unfrequently the same species which flourish on the hardest rocks abound also on trees. There can be no question, then, in such instances, of real parasitism. There may, indeed, be a few cases amongst those Lichens which are produced on tropical leaves, in which there is a certain connection between the tissues of the matrix and parasite, for several of these approach very nearly to Fungi; and some of the cortical species (also allied to Fungi), common both to the new and old world, are certainly very intimately connected with the bark, without, however, destroying the subjacent tissues; yet, in general, it may be said of cryptogamic plants, with the exception of Fungi, that they merely choose other plants as a base on which to rest their fronds, without, in the majority of cases, having any but the most superficial union. In the officinal barks, for instance, those specimens which are covered with healthy Lichens abound in the peculiar principles which make them valuable as medicines, while those portions which are covered by the beautiful Hypochnus rubro-cinctus, and other Fungi, are totally worthless, because their tissue has been penetrated and preyed upon by the mycelium, or in other words, the delicate rootlets of the Fungi. Still, it must be confessed that where the growth of trees is slow from an ungenial soil, or where the atmosphere is such as to encourage the development of Lichens on the smaller fruit-bearing shoots, their fertility is often very much injured. This does not appear, however, to be always the case. In the deep recesses of large woods very vigorous trees are often found much covered by Lichens, and Meyen tells us, that in the Riesengebirge and the Harz mountains, the Firs in the neighbourhood of little waterfalls are absolutely covered with Mosses and Lichens, and yet grow with the utmost luxuriance; and it is notorious that in tropical woods, a single stem in the most vigorous health often bears upon its trunk and branches a whole garden of Ferns, and other false parasites, without the slightest injury. Most gardeners, however, must know by experience that old fruit-trees which have become covered with the common yellow Lichen (L. parietinus), and scarcely produce any fruit, will, if carefully cleaned, recover sometimes much of their former vigour, sending out new shoots, and producing abundance of excellent fruit. In such cases, it is probable that the Lichen prevents the proper action of the light upon the tender bark of the terminal shoots, and thus weakens the buds, or by encroaching on the buds themselves, destroys them. This may not always be the case, and trees almost smothered with Moss and Lichen may be excellent bearers; but if so, it is probable that this arises from the strength and healthy state of the roots, and the genial nature of the soil, which makes the buds so vigorous that the new shoots outstrip the Lichen. Where it is thought necessary to prevent the growth of Lichens and Mosses on trees, the best method, perhaps, is to use a wash of quicklime, which has the advantage of destroying a large number of insects, if it does not at all benefit the tree directly. Except in the case, however, of fruit-trees, this indirect benefit hardly compensates for the loss of picturesque effect; and to the more attentive observer few objects, even amongst phœnogamous plants, present more beautiful forms, or more admirably blended colours, which in some cases are of great brilliancy, than many of these humble productions, which so often entirely escape the notice of the casual eye.—*M. J. B.*

ON THE PRESERVATION OF FRUITS.

THE preserving of fruits forms an important part of the art of gardening, but it is in very few places that sufficient attention is paid to it, for in many gardens, after the fruit has been gathered, and that not in the most careful manner, it is carried into the fruit-room and there laid upon the shelves, sometimes covered with hay or straw, and sometimes exposed to the atmosphere of the house. Nothing can be more injurious to their keeping than being subjected to all the currents of air to which the house or room may be exposed.

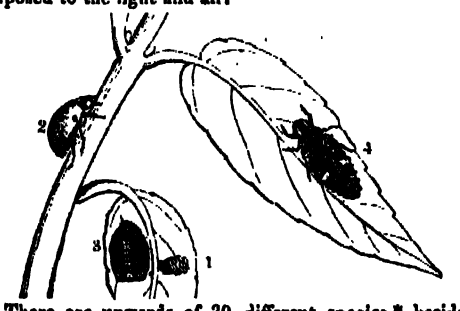
Many contradictory opinions are given on this subject by different authors, but they all seem to arrive at this conclusion, that the prevention of excess of air in the room where fruits are kept, is the most important point to be attended to, and is generally the least regarded. Some persons recommend packing the finest fruits in earthenware jars amongst moss, and excluding

the air by stopping up the mouths of the vessels, and then plunging them a foot deep in dry sand, in preference to keeping them on open shelves in the fruit-room: but mass is objectionable, as it communicates a musty flavour to the fruit. Sand has been adopted with success in the following manner:—Having procured some air-tight vessels, of any description or size, then put in a layer of sand, and a layer of Apples or Pears alternately, until the vessel is full; the sand must be well dried before being used, either by exposure to the sun or by fire-heat. After the vessel is full the lid should be perfectly secured to prevent the admission of air, by means of a piece of oil-cloth or leather, made larger than the rim of the vessel, so that it may lap over three or four inches; then take a piece of strong string and tie it after the manner that housekeepers tie up their pots of jelly. Some prefer sealing the lids, but this is attended with a disadvantage, as the covering is required to be removed every time that fruit is wanted. After the vessels are all properly secured, they should be placed in a cool airy room or cellar, with a temperature varying from 32° to 40°. There should be vessels of different sizes, for the different varieties of fruit, and on no account should more than one sort be put in each vessel, as some kinds ripen sooner than others. Each vessel should be numbered to correspond with a list of the sorts, so that it can be easily got at when wanted.

If there is not the convenience of a room, the vessels containing the fruit may be plunged in the open ground to the depth of from four to five feet; there they will be secure from any sudden change in the atmosphere. After the hole is made, put in a layer of charcoal, and then insert the vessel, filling up the intervening space with charcoal, pressing it firmly with the foot; the charcoal will be found to keep all cool and clean.

Amongst the numerous materials employed in preserving and packing Apples and Pears, I am not aware that charcoal has been employed; but it will be found upon trial to answer as well, if not better, than sand, as it is not so liable to absorb moisture. In the use of charcoal instead of sand, I would recommend it to be ground fine and sifted over the Apples as they are laid in, which should, in all cases, be done in the most careful manner, as the least bruise in one will spoil all.

The late Mr. Knight, in one of his papers in the "Hort. Soc. Trans." says, "The most successful method of preserving Apples and Pears, which I have tried, has been placing them in glazed earthenware vessels, each containing about a gallon, and surrounding each fruit with paper; but it is probable that the chaff of Oats, if free from moisture or any offensive smell, might be used instead of paper, and with much less expense or trouble. These vessels being perfect cylinders, about a foot each in height, stand very conveniently on each other, and thus present the means of preserving a large quantity of fruit in a small room. If the spaces between the top of one vessel and the base of another be filled with a cement, composed of two parts of the curd of milk and one of lime, by which the air will be excluded, the later kinds of Apples and Pears will be preserved with little change in their appearance, and without any danger of decay, from October till February and March. A dry and cold situation, in which there is little change of temperature, is best for the vessels. I have found most Pears to be greatly improved by their being taken from the vessel about ten days before they are wanted for use, and kept in a warm room; for warmth at this, as at all other periods, accelerates the maturity of the Pear." Here, then, we have the following important information, viz., the exclusion of air, and a low temperature, as the principle for keeping or retarding the ripening of fruit, and warmth for bringing it to maturity. The latter may be done at any period after the fruit has been gathered, by placing the vessels in a temperature of 60° to 70°.



I, however, differ from Mr. Knight in the use of Oat-chaff and paper; in the first case, it is difficult to procure the chaff of Oats free from moisture or an offensive smell, of which the fruit is sure to partake; and paper, except what is generally termed silk-paper, imparts a disagreeable flavour to the fruit. In fact, paper should not be used at all, for it is apt to damp and destroy the fruit in whatever situation it may be placed.

The fruit-room should be fitted up exactly like a pair of bed-room drawers, of some hard wood. Fir, being apt to spoil the flavour of the fruit, should never be employed. These drawers must be made to fit as tight as possible, in order to exclude air, and should be numbered in regular order, to correspond with a list which should always be kept in the fruit-room. When all is ready for the reception of the fruit, place in each drawer a quantity of fine dry sand or charcoal, then a layer of Apples, until the whole is full; then shut up the drawers and let them remain until the fruit is required for use; if any are wanted let them be taken out some days previously and placed in a warm room, or hothouse, until they are fit for the table. The advantage of such a fruit-room must be obvious to every practical gardener. First, we have the entire prevention of air, which is allowed by all to be injurious to their preservation; second, the sand or charcoal checks the evaporation of the fruit, thus preserving their flavour, and at the same time any moisture yielded by the Apples is absorbed by these materials, so that the Apples are kept dry and mustiness is prevented. The fruit preserved in this manner will be found as fresh in May and June as when first put in.—*J. McIntosh.*

ENTOMOLOGY.

THE SEVEN-SPOTTED LADY-BIRD, named *Coccinella septem-punctata*.—No one connected with the country, or who takes the slightest interest in the cultivation of a flower, can be ignorant of the services rendered to him by the pretty lady-birds, which have even escaped the sad prejudices of our nation as regards insects, so that children caress these handsome and most useful creatures in England, and in France they seem to be equally esteemed, being called *Vaches à Dieu*, and *Bêtes de la Vierge*, cows of God, and insects of the Virgin. It seems, however, that many persons are unacquainted with the early stages of their existence; and as this has led to the fatal error of destroying the larvæ, which are amongst the most valuable aids the cultivator has, in keeping under the aphides, it becomes very important that the farmer, as well as the gardener, should be at once enabled to distinguish his friends from his enemies.

If we examine the underside of the leaves of Turnips, Hops, or any plants, where they are greatly infested with plant-lice, we shall be sure to find little clusters of orange or buff-coloured eggs (fig. 1) deposited close together on their ends, and considerably resembling those of the White Cabbage butterflies at the first glance, but they are very different when magnified; they are more elliptical, fleshy, and smooth, not being sculptured as those of the papilios are. The first brood hatches in May, when the pearly empty shells alone remain, and the little black animals issuing from them run over the leaves in search of food; at this time they are rough with hairs, and have six short strong legs; as they grow they change their skins, and eventually those of the largest species (C. 7-punctata) attain the length of five or six lines (fig. 2); the larva now has a slate-coloured skin, smooth but dull; the body is attenuated towards the apex, and extends far beyond the six black sprawling legs, so that it looks like a little gay alligator, which it likewise resembles in its voracious and carnivorous habits. The head is rather small, trigonate, and of an orange-colour, but black at the base, the little black eyes and antennæ being scarcely visible, but the mouth is well developed; the black palpi are comparatively large, and the two rust-coloured jaws sharp; the 1st thoracic segment is broad, of an orange-colour, with a black spot on the centre and one on each side; these are covered with rough tubercles terminated by bristles; the two following thoracic segments are broad, with spined black tubercles, and the nine abdominal ones are shorter, each having six spiny tubercles forming as many lines down the back and sides; they are very black, excepting the lateral ones on the 4th and 7th segments, which are bright-orange; the six legs are shining black, tapering, bristly, and terminated by a single claw. When these larvæ are full fed, they attach their tails to the leaf on which they lived, or seek some more sheltered situation in the bark of trees or under paling, especially those which are to rest through the winter, and pass into pupæ (fig. 3), which are somewhat oval and convex, black, variegated with yellow and orange; in this state in spring and summer they remain only 12 or 14 days—probably less in fine weather—when the skin bursts down the thorax, and the perfect lady-bird issues forth, of a pale yellow or ochreous colour, gradually assuming its natural tints of red and black, as it is exposed to the light and air.

There are upwards of 30 different species,* besides endless varieties of these useful and beautiful little animals inhabiting this country, one of the largest and most abundant being the lady-bird with seven spots, called by Linnæus Coccinella septem-punctata. It is oval, convex above, flat beneath, shining, and black; the antennæ are short, clavate, and 11-jointed; the jaws are strong and sharp, and the palpi large;† upon the head are two white dots, and there are two larger ones on the anterior angles of the thorax; the elytra are bright brick-red, with seven black spots, the 1st upon the base of the suture, the others forming two triangles; wings two and ample; the tarsi are 4-jointed and terminated by two claws (fig. 4).

There is a smaller species, named C. dispar, or C. bipunctata, often with two black spots on the red elytra, but sometimes black with red spots, which is equally abundant. The lady-birds are probably to be found during the whole year, as they winter under bark, in chinks of posts, paling, &c., and are seen in the earliest days of spring, if the weather be fine, and late in the autumn also. I have met on the sea coast in September with immense numbers, which I imagine had deserted the Hop-grounds and were about to offer their good services to the farmer in his Turnip-fields.

The vast quantities of aphides which the larvæ of the lady-birds destroy cannot be calculated, for they seem never to cease from feeding, except when they are moulting, and consequently increase very rapidly in size; and the ladybirds themselves are equally active. One sees these pretty scarlet animals running over the plants until they meet with an aphis, which they immediately seize with their broad feelers, and keep squeezing out the saccharine contents, until the crumpled skin alone remains; they then attack another, and will thus proceed until, leaf by leaf, the plant is freed from this disagreeable and destructive blight. I was astonished to see how rapidly one of these little creatures picked up and ate the small apterous aphides on a Pelargonium, at the rate, I should say, of three or four in a minute; and a pair which I placed upon two Pelargoniums, cleared off all the plant-lice, with which they were greatly infested, in the course of 24 hours, so completely, that I could not find a living specimen. On the Continent their valuable services are so well understood, that the lady-birds are collected and placed upon Rose bushes, &c. to extirpate the aphides.—*Ruricola.*

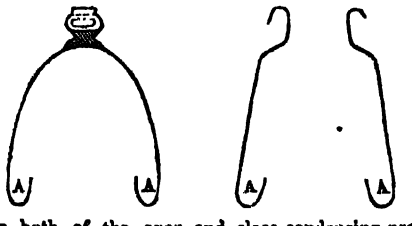
Home Correspondence.

The Hyssop of Scripture.—At p. 556 appears an interesting article on the Hyssop of Scripture. Its object is to prove that the Caper-plant is that Hyssop. Professor Royle has argued very ingeniously, and it is not my present purpose to dispute his general conclusion. I only wish to make a few observations on the last point of resemblance adverted to by the Professor. He seems to have found most difficulty in explaining how the Caper-plant would yield a stick long enough for a man to lift a sponge upon it to our Blessed Saviour's lips. Now, I am of opinion that there is no necessity for supposing that the stick was of Hyssop; indeed, it appears plain to me that it was not. St. Matthew and St. Mark both say that the sponge was put upon a reed; St. John alone mentions that they put it upon Hyssop. But a very obvious way of reconciling both, is to suppose that the sponge was placed among the small twigs of a bunch of Hyssop previously tied to a reed, and so lifted up to our Blessed Saviour's mouth. The bunch of Hyssop would not only safely support the sponge, but its twigs and leaves would receive the vinegar which might drop from the sponge, and prevent its running down the reed, and annoying the soldier who held it. St. Augustin is clearly of this opinion; for, having previously said that the sponge was put upon some Hyssop, he writes thus:—"Nor need we wonder how the sponge could be put up to his mouth, ... for, as we read in the other Evangelists, which this one (St. John) omits, it was done by means of a reed *. The very learned and acute commentator Estuis † inclines to what he considers a very probable opinion, that the Greek word in St. John, ὑσσώπῳ (*Hyssopo*), is an erroneous reading, and should be ὄσσῳ (*Hysso*), which means a spear-handle or a long stick, and which corresponds with the word *reed*, used by the other Evangelists. This would do away with the Hyssop altogether. But we may also very probably conjecture, with another very useful expositor whom I have examined, that a soldier very naturally used his lance, which was ready in his hand, on this occasion, and that this was meant by the word καλαμος, used by St. Matthew and St. Mark. For, though this word is translated a *reed*, it was very commonly used for a lance or spear; and it is very fair to suppose that the soldier would fix the bunch of Hyssop on the point of his lance, and so raise the sponge to the lips of our crucified Redeemer.—*F. C. Husenbeth, Cossey, near Norwich.*

Valerian Root.—Your correspondent, "A.H.," has been singularly unfortunate in the experiments he has made, with the view to ascertain if cats are enamoured of Valerian. This fact, I beg to observe, is undoubted. I verified it myself about three months since, and it stands thus entered in my Note-Book.—"May 21st. Purchased at Covent-garden market a root of Valerian, quite fresh. Conveyed it home mysteriously in an omnibus, much to the horror of the passengers, who eyed the bag in which it was contained as if it would breed a pestilence. Several parties quitted the omnibus abruptly, sniffing, and casting a look behind them not readily to be forgotten. I sat by, unmoved as a stoic, of course disclaiming all connection with the bag. Arrived at my journey's end, I hastily dismounted, dragging my charge after me, and was soon lost to sight. At night I tied the Valerian up in two sheets of thick brown paper, suspending it about 18 inches from the ground, and fastening it round the root of a tree. In the morning I found the paper very much torn and scratched. It exhibited, too, distinct traces of the various cats' teeth that had been engaged on its destruction during the night. Early next morning I contrived, unnoticed, to watch the passing scene. There sat seven sleek grimalkins, evidently in high enjoyment; while an eighth (no doubt a tom-cat), was rolling himself over and over on the Valerian, which was now strewn all over the ground. In a few minutes the whole were in a wonderful state of excitement, their festival terminating with a chorus, the harmony of which caused me to issue instantaneously from my concealment, and liberally reward the performers with the handle of a long rake. By this exploit I effected the 'lay of the last Minstrel!'"—*William Kidd, New Road, Hammersmith.*

Growth of Trees.—In the *Chronicle*, p. 541, there is a short article headed "Growth of Forest-trees." To me it is not satisfactory. We all know that if a tree is fastened to a wall, we never see the shreds moved upwards by the elongation of the stem; or when the stem gets to the coping of the wall, I never knew of the coping being moved by the pressure. We see plenty of strong shoots issuing from the old wood, but I do not believe that the old wood ever elongates.—*A. S.*—"A Subscriber, Ireland," states on this subject, that the result of his experience causes him to doubt the generally rumoured opinion that wood lengthens after being formed. In opposition to this, I will mention a fact that has come under my own observation. In the month of July,



* S. Augustinus in Evang. Joann. Tract cxix. de Cap. 19.
† Estuis in loca difficiliora S. Scripturæ, in Joan. 19.

1839, whilst looking at a fast-growing plant of Abies Deodara, in my plantation, a friend who was with me remarked, that the top shoot of the year was going up with two leaders, and immediately removed one with his fingers, just within his reach. The annual growth of the tree in question, in height, is well defined; and now in 1844, the bottom of the leading shoot of 1839 appears out of the reach of any man of the common stature. It may be said that in so trivial a circumstance as pinching a shoot off a tree, I may probably be mistaken in my date, but the fact is, I made a memorandum at the time of my friend's visit; and he was never here before, nor has he been since.—*A Subscriber.*

Mulberry-trees.—A correspondent, p. 523, speaks of having a fine Mulberry-tree about 200 years old, of which he appears (and most justly) proud: he adds that the alterations he is obliged to make will compel him to bury the root five or six feet below the surface of the ground. These alterations will inevitably be fatal to the tree, for the root of the Mulberry cannot bear that pressure. He has, therefore, no alternative but to remove it, and he must then remember that he is dealing with one of the most difficult plants he possesses, at a very advanced age, and in the removal he must have the hand and eye of the master assisting. If autumn is the time for the removal, he should first select an eligible situation to which to remove it, and, taking the tree at the size he describes, make a pit in a circular form, six yards in diameter and two feet deep; and if the bottom of the pit is not congenial, as for instance gravel, tile it, then put in about three or four inches of the best fine-riddled loamy soil that can be got—nothing is better than old rotten turf; the bed being now ready for the plant, take care to have an ample quantity of good materials at hand for filling up the pit. These things being finished prepare to take up the tree, by removing the soil to the extent of six yards all round the trunk, until you lay the main roots bare; erect three poles round the tree to be raised with a pulley, which must be fastened carefully to the tree under the main branches; give the pulley a steady pull, and ascertain whether you can raise the tree, but by no means force it or tear the roots. If you cannot stir it, secure the pulley where it is, and ease the roots of the soil with increased care, then try the pulley again: repeat this every two hours, adding additional caution as you get the finer roots, and always take care to bind your pulley, as this will always show you the resisting root, and call your attention to the point where your careful exertions are wanted; in this way you will raise the tree, but do not let it fall from the pulley poles. When it is up take it to the place where you intend to plant it with as much care as that with which you took it up, and lower it in the way you raised it, taking care to place all the roots in their natural position and at ease; then cover the roots three or four inches thick with the same sort of soil as you have under it as lightly as you can, keeping the tree perfectly steady. Now water moderately with guano water, and lay on about four inches of loose warm stable manure, and in like manner proceed until you get to the surface, always before watering raising and settling the tree a little so as to let the soil to the roots. In the upper layers use any compound that is at hand, which is light and nourishing, with either slaughter-house, pig, or artificial manure, and then bank it up and turf securely, steadying the tree with three or four props for the winter, and covering the whole up with two or three feet of warm stable manure, which should be exchanged from time to time during the winter. Give the roots at intervals a moderate watering by removing four turfs and putting in about four bucketfuls of sockage-water, chamber-water, or guano-water. In this way I removed two large Nut-Almond trees about three years ago, larger than what "A Correspondent" describes, and they did well; the year before they had fine full-grown shelled nuts. Some years ago the Duke of Devonshire also removed a much larger tree than the one described at p. 523, from Derby to Chatsworth, a distance of upwards of 25 miles, with success. About 18 years ago I removed a fine Yew, of more than 20 years' growth, from a distance, with complete success, and it is now a very fine tree; it required my personal attention for two years.—*J. W. Buchanan, Nuneaton.*—Another correspondent writes as follows:—If a very large limb of the Mulberry-tree is well stocked and planted, it will take root and grow very well. I imagine that "A Correspondent" may hasard the burial of his old friend, and proceed with his improvements. Having had much to do in planting and laying out grounds, it has happened frequently that I have buried many trees 3 or 4 feet in the soil. Old trees in many instances died—young ones in most cases flourished the more. Young trees, but more particularly Poplar, Elm, and Beech, will throw out rootlets 3 or 4 feet above what before sustained and supported life. I have never found that Oaks liked the operation of covering in and embedding them to any extent, except in a small way, viz., in making roads on the slopes of planted hills: the soil thrown on the lower side amongst them always gave them fresh vigour, as it does all trees, even the Fir tribe.—*K.*

Van Mons's Pears.—Your remarks on the best mode of improving the fruit of Elæagnus parvifolia brought to my recollection the principles on which Professor Van Mons, of Brussels, the producer of so many of the fine new Belgian Pears, proceeded in obtaining them, which, as I had the details from his own mouth, may be worth stating, especially as I do not recollect to have seen a distinct explanation of his views in any English horticultural work. He paid no attention to impregnation with the pollen of superior sorts, as practised by Mr. Knight, nor, as far as I remember (though on this head will not speak positively), did he care whether the pippins which he first sowed were of Pears of first-rate quality or not. His great object was to raise a large stock of young seedlings. From these (of which he showed me probably a quarter of an acre, growing in the rich alluvial soil of his nursery, in the lower part of Brussels), he selected those plants which, from their vigour of growth and largeness, and (I think) thickness of leaves, he judged likely to answer his purpose, and transplanted them (I incline to believe more than once, to hasten their blooming), waiting patiently the six, eight, or ten years that elapsed before they bore fruit. He did not care of what quality this fruit proved. He sowed all the seeds of all the kinds, and again selected the best plants. These again were transplanted, and usually bore fruit after a less number of years' growth than the first generation, and several of the Pears always proved of good quality. But a third sowing and similar selection and treatment were necessary to obtain his finest kinds, and almost the whole of the produce of this third generation was excellent; and it was in this way he raised his Marie Louise, and other fine sorts. Thus, as far as my recollection serves, his great principle was to select from successive generations, out of a large stock of seedlings, those which from long observation he knew would be most likely to produce good sorts, and it was not till the third generation that he calculated on producing first-rate fruits. He told me that he had originally been led to follow this plan from his experience in raising Roses from seed, of which he had gained many fine varieties, and he pursued a similar method in obtaining new Apples. Might it not be worth while to add to the course of treatment which you have so well pointed out for Elæagnus parvifolia, the selection of the most vigorous and promising plants for two or three successive generations from seed? And probably a similar selection might also be important in trying to raise improved varieties of Raspberries, Currants, &c.—*W. S.* [We have before heard something of this plan: but it is to be remembered that Dr. Van Mons obtained very few good Pears out of thousands of seedlings; and that Mr. Knight obtained very few bad ones out of a very small number of seedlings. We prefer our own method.]

Bulb Water Cucumber Glasses.—I some time ago made several experiments with these, in opposition to the dry cylinder. I found that the fruit in the bulb glasses, after ten days' growth, was about one-third longer and twice the weight of those grown in dry cylinders; and finding that with these advantages the quality was not injured, I proceeded last year to make various experiments upon Peaches, Pears, and Grapes. The constant evaporation of water upon the fruit increased the size of the Peach, but injured its flavour; upon the Pear no beneficial effect was apparent; the Grapes were, in some instances, improved in size and quality; those that hung nearest the water were preferable, and some of the berries at a distance from the water prematurely decayed. In the meantime, however, my object in writing is to call attention to a propagating glass (which I have constructed constantly to evaporate water by heat, and condense it by cold alternately), for keeping the cutting or plant in a constant state of moisture, similar to Ward's cases. I have placed a few in the hands of my gardener, who reports favourably of them. The accompanying is

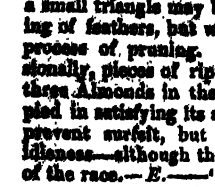
a plan, both of the open and close condensing propagator. The close condenser, No. 1, should be somewhat of the form of a conical dome, or between the cone and the parabola, in order to allow of the drip, on adhering to the interior of the glass, to descend into the channel A, for the reception of the water; the channel being once filled needs no farther attention, as the diffusion of moisture by heat, and its return and alternate condensation, not only feeds with moisture the plant or cutting more regularly than by syringing, but by its condensed particles adhering throughout to the interior surface of the glass, the drip is prevented. No. 2 is an open condenser applicable to Grapes, either in or out of the house; it would require more frequent supplies of water than No. 1, as the greater portion of the water would fly off by evaporation, and would not be condensed again into the glass. Ribbed glasses are perhaps preferable, for preventing drip, to plain glasses.—*Apsley Pellatt, Falcon Glass Works.*

Asparagus, &c.—"If you please, Sir," said my gardener to me a day or two ago, "I want some more salt." "Salt!" I replied, "have you not plenty of liquid manure fixed and prepared with sulphuric acid? What can you possibly want with salt?" "Why, Sir," returned the man, "we want that too; but you know, Sir, you said in the spring, that we never had such fine Asparagus before, and depend upon it, it was all owing to that 'ere salting we gave the bed last year." I quite assented to the fact and the inference, and more salt was ordered. I was turning away, when the man again arrested my attention: "We must not make the new Asparagus bed yet, Sir?" "And why not?" I replied; "the weather is fine, and you have plenty of dung?" "Why, you see, Sir, them young plants a'n't done growing yet; and as we had such a capital crop of Strawberries because we didn't cut off the leaves, I should think what's good for the Strawberries is good for the Grass; and John Squinell killed all his Asparagus by cutting off the tops in June." Here are two practical proofs of the value of the advice contained in the *Gardeners' Chronicle*, viz. the salting of Asparagus, and not cutting off the leaves of the Strawberries. I give the colloquy as it occurred, because the testimony is all the stronger for being unsought. Your correspondents who have failed in the use of salt, have doubtless applied too much. The quantity I used to my bed was a pound to every square yard, applied after cutting off the tops, and early in the spring in rainy weather. With regard to the Strawberries, I think my gardener's argument unanswerable—"What's good for the one is good for the other." I certainly never had such fine plants in the spring, or better crops in the summer, than I have obtained since I left the leaves alone. Can you explain the reason why Myatt's Eliza has completely failed this year, both in my own and neighbour's garden? The stock was good and true, and bore well last year; but this, I have not had a dozen fruit on three beds.—*C. R. Bree, Stowmarket.* [Dry weather?]

Destroying Wasps.—Your correspondent's plan of putting the spirits of turpentine into a bottle instead of into a cup, is a decided improvement. If he has an opportunity of doing so, would he try a plan I have suggested more than once, but do not know whether it has yet been tried? Let a small quantity be squirted into the hole as far as possible, and then let the hole be blocked up with clay. It is possible the soil may imbibe so much of the turpentine as to prevent success, but the experiment is worth trying.—*J. S. Henslow, Hitcham.*

To destroy Ants.—"It happened that a piece of camphor was laid in a drawer containing sugar, and which was sadly infested by ants. On opening it a few days afterwards, the bottom of the drawer was literally strewed with dead ants. The experiment was repeated with success—a small piece of camphor placed in a corner of the drawer being quite sufficient. Camphor dissolved in alchohol and diluted with water might destroy them if sprinkled on trees or walls, or if poured into their nests."—*John J. Godfrey, Albany, New York, March* 3, 1832. "Proteus" forgets where he met with the foregoing extract, neither has he tried it; but, concluding from late Numbers of the *Chronicle* that the destruction of ants is an object of interest to some of his fellow-subscribers, he contributes his mite to their service.

Sting of a Bee.—I beg to inform a correspondent in a former Number, who applies for a remedy for the sting of a bee or wasp, that the application of a washerwoman's blue-bag, moistened, is the best remedy, and acts almost like a charm instantaneously; "it is far preferable to liquor potassæ, or any alkaline solution.—*Medicus Corvagiensis.*



Gooseberry Caterpillar.—Being for many years annoyed by this destructive pest, I have endeavoured to get at the root of the evil by studying the habits of the insect. In a flower-pot filled with earth, and covered by a finger-glass to prevent the caterpillar wandering, I placed on a leafy slip of the Gooseberry tree six caterpillars, supplying them every second day with a fresh sprig, and thus watched their progressive changes until they dropt from the branch, and buried themselves. In this manner I discovered that there are two seasons in the year for the ravages of this pest. The first caterpillars appearing about the middle of May, and eating for five weeks, in this time the usual mischief is done, and the fruit is destroyed, unless the trees are carefully picked; but I imagine that few persons are aware that the evil is only half met by this one picking. The Saw-fly (Nematus Ribesii), according to Stephen, again emerges from the pupa state in the beginning of August, or a few days earlier, according to the season; and after having again defoliated the trees, deposits itself in the earth until the May of the following year. The early decay of the Gooseberry leaf—the indifference about the tree when the fruit is gone by—may be the cause why this second swarm is not taken notice of; but certain it is that on the second picking depends the extent of the plague for the next year. If then carefully picked there will be no larvæ in the ground for the next season. If neglected, the increasing plague of insect life goes on. Two successive years of autumnal picking, I can say from my own experience, will banish the Gooseberry caterpillar, though one careful looking over the trees on the third year in autumn may not be misplaced. Perhaps gardeners are not aware that seedling Arbutus are a favourite food of the same caterpillar.—*A Lady Gardener, County Cork.*

Sporting Character of the Peach.—A rather curious instance of this has occurred here. A Peach tree—the Vanguard—has produced a very fine red Roman Nectarine. The Peach tree has a fine crop of Peaches, and the Nectarine looks singularly curious among the Peaches. In what way can you account for it? I never saw anything of the kind before.—Did you?—*M. Busby.* [Yes—often. These occurrences are called sports, and it was doubtless thus that a Nectarine was first obtained.]

The Gray Parrot.—In reply to "A Constant Reader," I would mention that a good way for preventing a favourite bird from picking off its feathers, is to brush or rub the parts that it is fondest of picking with a strong solution of bitter aloes soaked in water. If this is done for a short time I imagine the bird will soon desist from playing these tricks.—*M. H. W.*—Another correspondent remarks that the bad condition of "A Constant Reader's" bird is occasioned by "want" of "attention to diet." "Bread and milk, chicken bones," &c. are not to be met with every day in the African woods.

Discard this system, and begin by giving a drop or so of castor oil dabbed on a small piece of bread, previously saturated with honey or with sugar and water. Remove with a sharp file the apex of the lower mandible, so that a small triangle may be formed; this will stop the drawing of feathers, but will not interfere with the necessary process of pruning. Feed on Hemp-seed, with, occasionally, pieces of ripe fruit, and now and then two or three Almonds in the shell. The time necessarily occupied in satisfying its appetite with the seed will not only prevent surfeit, but will stop the screaming through idleness—although the gray parrot is not the most noisy of the race.—*E.*——"A Lady" writes—"I purchased a gray parrot that had scarcely a feather, and it continued to pluck them until it was taken off all greasy food, also meat, and even bones, as the marrow gives them a taste for blood, and they will even pluck their feathers for the sake of the blood at the roots: they will lose this habit after a time, should this plan be strictly adopted:—Capsicum twice a week should be given till they assume a healthy appearance. Seeds are what they like. My bird in a few months had a fine plumage."——Another writer recommends change of food, viz., bread scalded in water, Indian corn, and occasionally a few Almonds. The heat of the skin is the cause of Poll's troubles. It should also have tepid water to wash in, and should always be kept out of draughts; the latter are most injurious, and generally fatal to the tribe, or any birds accustomed to a warm climate.—*Falcon.*——A fifth correspondent, signing himself "Medicus Corcagiensis," says that "A Constant Reader's" treatment of his parrot is the cause of his depriving himself of his feathers. The same writer states that animal food in any shape or form, if given frequently and long continued, will produce this effect.——Do not allow the gray parrot to pick any more chicken-bones, or any kind of meat; confine her strictly to bread and milk, and a little hemp-seed, if she will eat it. Ripe sweet fruit may be offered occasionally; give her now and then a shallow pan of water, tepid, to dabble about in like a duck. I should like to hear the result of this regimen in the course of two or three months.—*Psittace.*——Milk and chickens' bones are bad for a gray parrot, but particularly the latter. Parrots are fruit-eating birds, but, like their fellow bipeds, are fond of food that is not good for them. Animal food induces a feverishness in the skin, which causes them to pick their feathers; these easily come out, and they get a little soft picking on the ends of the quills, and thus it goes on till, unlike the Kilkenny cats, not even a vestige of their tails remain. They delight in a mealy Potato, or bread soaked in water, which agreed right well with one in my possession for some time.—*B. F.*——"N. S. H." asks, "If any remedy can be applied to prevent a favourite bird picking off its feathers?" To this I answer, No. This is one of the inveterate bad habits peculiar to some birds, from which they never can be weaned. Your correspondent will, I fear, have an unsightly bird to look upon, as long as his parrot survives, if, indeed, it is considered a matter of "necessity" to reckon him as one of the family, and so preserve his life. I have had several birds during the last six years, inoculated with this annoying propensity, and in every case I have found it expedient to shorten their lives. Their *personel* has rendered this a simple act of humanity.—*William Kidd, New-road, Hammersmith.*

Plan of keeping up a Moist Atmosphere.—"A." has found the following mode of maintaining a moist atmosphere, during the propagation of cuttings, successful:—

Reference to Plan.

a The cover of a handglass.
b The framework of ditto.
c A tray, or riddle, having a bottom made of copper wire, or perforated zinc, to receive soil wherein to plant cuttings.
d An earthen pan, filled with water.
e Cuttings.

Place the pan upon the ground, and the tray upon the pan, and over these put a handglass.

Foreign Correspondence.

Hong-Kong, March 21, 1844.—You have, doubtless, often heard of the celebrated Fatee Gardens, near Canton, the flowery land, as the name implies, from whence a great number of those fine plants were first procured which now decorate our gardens in England. They are situated two or three miles above the city, on the opposite side of the river, and are, in fact, Chinese Nursery Gardens, where plants are cultivated for sale. I visited them for the first time last summer, on my arrival in China, before proceeding to the northern provinces; and again a week or two ago. There, I suppose, I beheld a specimen of the far-famed system of Chinese gardening, about which we have heard so much in England, and of which I shall tell you something fully. The plants are principally kept in large pots arranged in rows along the sides of narrow paved walks, with the houses of the gardeners at the entrance through which the visitors pass to the gardens. There are about a dozen of these gardens, more or less extensive, according to the business or wealth of the proprietor; but they are generally smaller than the smallest of our London nurseries. They have also stock-grounds, where the different plants are planted out in the ground, and where the first process of dwarfing their celebrated trees is put in operation. These gardens contain large collections of Camellias, Azaleas, Oranges, Roses, and various other well-known plants, which are purchased by the Chinese when in flower. The most striking plant in autumn or winter is the curious fingered Citron, which the Chinese gather and place in their dwellings or on their altars, when it is much admired both for its strange form and also for its perfume. The Mandarin Orange is also much grown at Fatee, where the plants are kept in a dry state, and flower and fruit most profusely, producing large, flat, dark, red-skinned fruit. The Chinese have a great variety of plants belonging to the Orange tribe; and one which they call the Cum quat—a small oval-fruited variety—is most excellent in their preserves. The Murraya exotica, Aglaia odorata, Ixoras, and Lagerstræmia, are also very ornamental here in autumn. In spring the Fatee Gardens possess the greatest attractions. Now they are gay with Azaleas, Cydonias, double-blossomed Prunus, Judas-tree, Rubus rosæfolius, Bletia hyacinthina, Roses, and Camellias. The Azaleas are most splendid, and reminded me of the Exhibition in the garden of the Horticultural Society of London, only on a much larger scale. The principal kinds grown are Indica, Indica alba and phœnicea, lateritia, variegata, and the yellow Azalea sinensis. By the by, I found this plant wild on the Ningpo Hills, so that there is no doubt of its being a genuine Chinese variety—a fact which you seem to doubt in the "Botanical Register," where this plant is figured and described. The air at this season around Fatee is perfumed with the sweet flowers of Olea fragrans, and the Magnolia fuscata, both of which are grown extensively in these gardens. Dwarf trees, as you may easily imagine, occupy a principal station, and are highly prized by the Chinese; they are trained into the most grotesque and curious forms, resembling pagodas, dwelling-houses, and various kinds of animals; but during my stay in the town of Ningpo, in the north, I saw some which far surpassed any about Canton. These were Pine-trees, clipped and trained in the form of deer—horns, legs, eyes, and everything complete. A Mandarin there very kindly offered to make me a present of one of them, but I was obliged to decline his civil offer, as it was of no use to me, and as my collection of plants was already large, and difficult to move about with. The plants which stand next to dwarf trees in importance with the Chinese are certainly Chrysanthemums, which they manage extremely well—perhaps better than they do any other plant. So high do these plants stand in the favour of the Chinese gardener, that he will cultivate them extensively, even against the wishes of his employer; and, in many instances, rather leave his situation than give up the growth of his favourite flower. I was told the other day that the late Mr. Beale used to say that he grew Chrysanthemums in his garden for no other purpose than to please his gardener, not having any taste for this particular flower himself. Moutans are not natives of the South of China, but are brought down in large quantities every year, about the month of January, from the northern provinces. They flower soon after they arrive, and are rapidly bought up by the Chinese to ornament their houses, after which they are thrown away, as they do not thrive well so far south as Canton or Macao, and will not flower a second season. They are sold according to the number of flower-buds they may have upon them, many of them fetching rather high prices. One of the old gardeners here, whose name is Aching, does a considerable trade in seeds with the English and American residents; but, unfortunately, he has got a bad name, owing to his seeds generally failing to grow when they are sent home. It is now currently reported that the old man boils them, in order that his trade may not be spoiled by some enterprising propagator at home; but I do not credit any statement of this kind, and you will, therefore, confer a great favour on him if you will contradict this report, and save his good name. Although the botanist will find but little that is new to him in these gardens, yet they are well worth a visit; and in the spring months, when most of the plants are in bloom, they have really a gorgeous and imposing appearance, worthy of the poetical name of Fatee, or flowery land, which the Chinese have given them. The garden which formerly belonged to the East India Company is still in existence; it is but a small place on the river side, not more than 60 paces each way, having broad chunamed walks round it, and a clump, with a few trees in the middle, and a few more between the walk and the wall all round. Since Mr. Reeves's time no one seems to pay any attention to the plants here, and if there ever were any rare species, they are all gone now. A few Palms, Plantains, Magnolia grandiflora, Clerodendron fragrans, Justicia adhatoda, Ligustrum, Murraya exotica, the Lechee, and two or three other well-known things, are all that it contains. The factory itself is still in ruins, but the Consul is getting them cleared away, preparatory to the construction of new houses for the English merchants. In front of the American factory there is a very nice public garden, at least six times the size of the Company's, with fine broad walks for recreation, and containing numerous shrubs and trees indigenous to the country; nothing, it is true, of any rarity, but sufficient to make the garden look extremely well. A good garden and promenade is of much importance here; for it is likely to be some years before foreigners enjoy the same liberty at Canton as they do in the other parts of China.—*R. F.*

Societies.

BOTANICAL SOCIETY OF LONDON.

Aug. 2.—J. Reynolds, Esq., Treasurer, in the Chair. Mr. G. S. Gibson, and Mr. J. Tatham, Jun., presented specimens of a new British plant, Spergula stricta of Swartz (*Arenaria uliginosa*, Schleich. and Decand.; *Holosteum stricta*, Fenzl and Reichenbach), discovered by them in June last (in company with Mr. J. Backhouse and Son, and Mr. S. Thompson), near the top of Widdy Bank Fell, about ten miles west of Middleton, in Teesdale, and five from the High Force, in Durham; the elevation was about 1900 feet. The locality was confined to a very small space.—Specimens of Anemone ranunculoides, were presented by Mr. M. Stovin, found wild in a wood near Worksop, Nottingham. Specimens from this locality were presented in June last; and in a letter to the Secretary, Mr. S. observes, "The more I see and hear of this plant, in the Nottingham station, the more am I convinced of its being wild."—The concluding portion of Mr. Lees's elaborate paper, on the British Fruticose species of Rubus was read, and several specimens and drawings exhibited in illustration of the views contained in the Essays.

Rebietus.

The Favourites of the Flower Garden, arranged according to the Natural System of Botany. By G. Francis, F.L.S. 12mo. Simpkin & Co.

This little book is intended for the use of very young people, who desire to acquire some knowledge of Botany as an amusement, and it is well suited to that purpose. Compared with the juvenile introductions to the Linnean System of Botany, it is a considerable stride; and it shows most clearly how ignorant was that outcry which arose a few years ago, when it was first proposed to substitute amongst students, for the threadbare artificial arrangement of Linnæus, the more philosophical classification of Ray and Jussieu. People now inquire what the difficulties are which terrified the ancient Botanists of 1830, and wonder what their clamour was about. The fact is, that the one method of studying Botany is as easy as the other, if set about in the right way. The object of Mr. Francis is to point out that way, and he has done so zealously. We doubt, however, whether, for the purpose of teaching, the work is quite exact enough. However, it is only to be regarded as a preparation for further information; as the means, in fact, of exciting, rather than satisfying, a taste for the study of the common flowers of our gardens. By aid of an abundance of etchings and woodcuts, the subject is rendered so easy to understand, that the most dull of apprehension may quickly learn how to use the natural system for common plants. The Author's account of the Daisy will illustrate his mode of dealing with the popular part of his subject.

"Everybody knows the Daisy of the fields, and every one with the least taste for poetry must have read some little poem written in its praise; but our young friends may not be aware that the numerous varieties of Daisies found in the garden are all derived from this little wilding. These garden favourites are of much difference of form and colour; one variety is of a very dark-red, another of pink and white, others pure white, while a fourth kind has one large flower [head] and several smaller ones growing out of it; so that it has been compared to a hen surrounded by her chickens, and called accordingly the *Hen and Chickens Daisy*. These denizens of the garden have not, however, the charms of the wilder plant—they blossom but at one season, they are often killed by the drought of summer, and the damp of winter; but the little darling of the wild, and which has been emphatically called 'Nature's Favourite,' the 'Poet's Darling,' the 'Eye of the Day' ('Day's Eye' or 'Daisy'), and many other names, blossoms everywhere and at all seasons, suggesting a thought of innocence and home, for it is especially an English flower; and delighted must Dr. Carey have been to see one spring up in India, from among some other seeds brought from England. This circumstance has given rise to some exquisite lines by the poet Montgomery, which are too long to quote, but which conclude thus—

Thrice welcome little English flower,
To me the pledge of hope unseen,
When sorrow would my soul o'erpower
For joys that were, or might have been.
I'll call to mind how fresh and green
I saw thee waking from the dust,
Then turn to Heaven, with brow serene,
And place in God my trust!

"It was a delightful thought of the ancient Celts to suppose that the employment of new-born infants, removed to heaven, became henceforth the scatterers of flowers upon the earth. The virgins of Morven, to soothe the grief of Malvina, who has lost her infant son, sing to her:—'We have seen, O Malvina, we have seen the infant you regret reclining on a light mist. It approached us, and has shed on our fields a harvest of new flowers. Look, O Malvina—among these flowers we distinguish one with a golden disk, surrounded by silver leaves—a sweet tinge of crimson adorns its delicate rays; waved by a gentle wind we might call it a little infant playing in a green meadow, and the flower of the bosom has given a new flower to the hills of Cromla.' Since that day the daughters of Morven have consecrated the Daisy to infancy; it is, said they, 'the flower of innocence—the flower of the new-born.'

* * * That old favourite the Daisy, born
By millions in the balmy vernal morn,
The child's own flower.—*Carrington.*"

Garden Memoranda.

Groom's Nursery, Clapham Rise.—At this nursery there is now in bloom many large and well-grown specimens of all the varieties of Lilium lancifolium. Several of the plants are between 6 and 7 feet high, and, having from 8 to 10 stems, each producing from 12 to 20 fully expanded blooms, they present a most magnificent appearance. On one specimen of L. l. album, or speciosum, there are as many as 30 flowers and buds on a single stem. Not only are these Lilies extremely

handsome on account of their large showy blossoms of the richest colours, but they also possess an agreeable aromatic fragrance which adds considerably to their value. For decorating the greenhouse and conservatory at this season, when flowers are scarce, they are invaluable, as they keep in bloom for a considerable length of time, and in beauty they have no rival. It may be remarked that in some collections we have seen, scarcely two plants have the same shade and disposition of colour. There is a regular gradation of tints, from pure white to the rich colour of L. sp. rubrum. In some, the rich crimson spottings are more numerous; in others, they are larger; and in a few they are almost wanting. Mr. Groom, who is a most successful cultivator of these plants, has grown nearly all the kinds in the open air for three years, and he considers them sufficiently hardy to stand our winters, if planted in light soil, and at a good depth. This season he has large beds of them planted out, which are producing an abundance of bloom. Mr. Groom remarked that the plan he generally pursues in the pot culture of these Lilies is, to grow them in pots of a large size, having plenty of drainage, and to use peat only with a little fine sand for the soil. One great point is to keep the bulbs, particularly the largest, at a sufficient depth to allow soil enough above the bulb for the stem-fibres to grow freely. When they require repotting, which should only be performed whilst the bulbs are dormant, they should be turned out of the old pots, and have the crocks carefully removed, so as to avoid injuring the fibres, or even disturbing the soil. The bulbs are then to be repotted in a larger-sized pot in peat and sand, with good drainage. They are easily increased by placing some pieces of turfy peat round the stem at a sufficient distance to allow room for some finer peat to be placed next the plant. In this way a fine stock of them may soon be obtained.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

BERBERIS UMBELLATA. Umbellate Berberry. (*Hardy Shrub. Berberacem.* Hexandria Monogynia.—This is a hardly sub-evergreen bush, about three feet high, growing freely in the common garden soil, flowering freely in June, and easily increased either by seeds or layers. It was raised in the garden of the Horticultural Society, from seeds received from the East India Company, at different times, and under various names, but more particularly those of B. Wallichiana and floribunda. It is no doubt in many other collections under this or similar names. B. floribunda, however, has spiny leaves, not at all glaucous on the under side, and B. Wallichiana, which also differs in these respects, has sessile fascicles of flowers, and is quite another thing. This is easily known by its narrow, spineless leaves, slightly glaucous beneath when fresh, and becoming more so when dry. Dr. Wallich has distinguished a plant called B. angulosa from his B. umbellata, but our specimens of it from him present no tangible mark of distinction. As for the name umbellata, it is unfortunate that it has been introduced into systematic works, for the shortness of the racemes, from which circumstance it has been taken, is apparently accidental and unimportant.—*Botanical Register.*

GLOXINIA SPECIOSA. Garden varieties. (*Stove Herbaceous plant.*) Gesneraceæ. Didynamia Angiospermia.—1. Gloxinia magnifica. 2. G. insignis. 3. G. bicolor. 4. G. Carton.—"For the few last months our gardens have been furnished with some new varieties of this beautiful plant, which have excited universal admiration; especially those in which pink is the predominant colour. We have, therefore, thought it desirable to take advantage of an opportunity afforded by Mr. Glendinning, of the Chiswick Nursery, for bringing together the most distinct among them. The account Mr. Glendinning has given of their origin is as follows:—"These beautiful varieties were raised from G. speciosa rubra fertilised with the pollen of Sinningia guttata. The flowers, however, give little evidence of the male parent, although the branching habit which distinguishes Nos. 1, 2, and 4, are proofs of their alliance to Sinningia, particularly that of magnifiora, which has very hairy leaves and stems, and an erect growth. They were first raised in the gardens of the Duke of Northumberland at Syon, by his grace's gr., Mr. Carton, who has been long celebrated for producing various interesting novelties by hybridising. Plants of them were exhibited by me before the Horticultural Society in Regent-street, in June last, when they were awarded a Banksian Medal. The same individuals have continued to bloom ever since very profusely, and are now, August 14th, still in flower. On that account, as well as their great beauty, they are likely to prove permanent objects of interest in our gardens."—*Botanical Register.*

Miscellaneous.

Brazilian Beet, a Plant for either Kitchen or Pleasure-Gardens.—It is about 10 or 12 years since the Brazilian Beet (Beta braziliensis) was introduced into the gardens of Belgium; but there it was only considered as an ornamental plant, and the beauty of its leaves makes it certainly quite worthy of being so, for the golden-red and crimson-coloured ribs produce a beautiful effect among other plants. It does not, however, appear that, at present, anybody has ever thought of cultivating the Brazilian Beet as a vegetable; on the contrary, we have remarked that in most of the gardens where it was formerly cultivated it is now disappearing, to make room for other ornamental plants. Perhaps also, this plant is not a favourite with amateurs, as its flowers are rather insignificant. Before we speak of its cultivation, it would be better to give its description:—The root is fleshy, and divides itself in the soil; the leaves are from 16 inches to 3 feet long, according to the fertility of the soil and its exposition. The middle of the leaf forms a midrib from 2 to 3 inches broad, fleshy and succulent, and becomes thinner towards the top. It is yellow or red, and varies in all the shades of these two colours. The width of the leaf is 6 inches; the upper surface shining, puckered, of a beautiful green, crossed with veins of the same colour as the midrib. The stem developes itself the second year, and resembles in this, and also the flowers and seeds, those of the Garden Beet. It produces an abundance of seeds, and is consequently very easy to propagate. *Cultivation.*—To cultivate this plant, you must sow the seed at the end of March or beginning of April upon a cold bed, or a well exposed border; the seeds come up in about 8 or 10 days, and in three or four weeks the young plants are strong enough to be transplanted. To each plant is given 3 feet square of ground, if it is good and fertile; in a moderate soil 1 foot 8 inches is sufficient. The Brazilian Beet flourishes in almost all kinds of soils, but a maiden soil, composed of sandy loam, suits it best. During its vegetation, particularly at the beginning, it must be well hoed and watered in dry weather. It is not necessary to take away the weeds, because they are smothered by the large leaves of the Beet. *Uses.*—When the season is rather unfavourable the leaves may be cut off every five weeks, beginning in June, taking the outside ones, and leaving those which form the heart, or else cutting off the neck of the root, with all the leaves, which does not hurt the plant. It may be prepared for table like Spinach, in which case the green part must be separated from the leaves; the coloured ribs may take the place of Asparagus, and be prepared in the same manner, after they have been boiled in water; they may be eaten with either oil or vinegar; at all events the skins which cover them must be peeled off the ribs. In order to obtain this plant in winter, or early in the spring, it is necessary to make a seed-bed late in June or July; to prick out the young plants upon a cold bed, where they will remain until February; then they must be transplanted upon a hot-bed, where they will give an abundant crop. They may also be taken out in the autumn, before the winter sets in, and be planted in a cellar, where they will produce leaves during all winter, which may be eaten cooked or as a salad. We can recommend the cultivation of this plant, for its produce is not only sure, but as agreeable as wholesome, and in all respects deserves the preference to the common garden Chard Beet.—*Revue Horticole.*

The White, or Barn Owl.—Another species, the victim of all who, ignorant of his value, can get a shot at him. "As a constant destroyer of rats and mice," says the historian of British Birds, "the services performed by them for the agriculturist have obtained for them a toleration which they well deserve." I fear this remark applies to some very enlightened localities: here he obtains no mercy. The number of mice this bird must destroy is very great, as a vigilant observer has seen him return to his nest with his prey every five minutes. The gardener complains of the destruction of his early crop of Peas by mice, but he feels no hesitation or remorse at having a shot at the bird who would be of essential service to him in preserving his produce from these depredators.—*J. M.*

CALENDAR OF OPERATIONS
For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

THE beginning of September, when slight fires will be necessary in dull or cold weather, is a critical time for stove plants. The house must now be kept more close, air being given in the middle of the day only. An increase of heat by artificial means is more likely to retard the ripening of plants now than if they were left cool and dry: the thermometer should not, however, be allowed to fall below 60°: for the next six weeks, and during this time, it is of as much importance to keep the atmosphere of the house dry as in the dead of winter. These rules, however, do not apply to plants whose habit is to grow in winter, as is the case with many bulbs—Orchidaceæ and a few other plants. Clerodendron splendens is one which grows late in the autumn, and may now be encouraged; it will flower for a long time in winter, and established plants of it should not be forced to grow in the spring or early summer: like some other plants it requires a long time of rest after flowering.

Conservatory.—The management of the conservatory will be more uniform now than in summer: no syringing will be necessary unless for a plant here and there, which may require it for keeping down insects; where blinds have been in use to keep off the sun they cannot be dispensed with yet altogether, but use them as little as possible from this time; get all the watering done in the morning, and give no more of it to any stove plants which are brought into this house for their flowers than just enough to keep them from drooping their leaves. The few species of Lantana which we cultivate in this country are well suited for flowering in this house late in summer and through the autumn, and there is no doubt but some kinds of them would interbreed and make fine hybrids. There are between 40 and 50 sorts of Lantanas in the Berlin Botanic Garden, many of which, no doubt, would be welcomed in this country, and might easily be procured through the nurserymen. The old Turnera elegans is a very useful and gay plant: it flowers from April to October in the conservatory, and even out of doors in summer; but it requires a house rather warmer than a greenhouse in winter, and is the first to go off in damp winters. Young plants of it in small pots, well drained, and filled with sandy loam only, might now be put in a spare melon frame to ripen them off; when they have filled the pots with roots, harden them by admitting plenty of air. In winter place them on a shelf near the glass, in a cool part of the stove.—*D. H.*

II.—FLOWER GARDEN AND SHRUBBERIES.
Out-door Department.

Now that the weather is so fine it will be as well, where such convenience is requisite for the preservation of the more hardy of the tender plants through the winter, that provision be made for the formation of a good-sized temporary pit. Turves of dry peat, where they can be readily procured, are as good a material as can be used, but in the absence of them, turves of a loamy nature will be found a good substitute. The situation where the pits are built should be dry and sheltered, and the turf walls should not be less than fifteen inches thick. Make the walls firm as you proceed, and when of the requisite height dress the sides off square and neat with an old hay knife, or some such instrument. The top layer of turves must be secured in their places by driving pegs through into the lower ones, and if the whole of the walls of a pit of this kind could be covered with Croggon's Patent Asphalte Roofing, which is a very inexpensive material, they would be rendered doubly secure, as so long as they are dry there is no fear of frost penetrating; but if they become wet, which the asphalte would prevent, their protective influence would be materially deteriorated. I intend, as an experiment, to build a pit with mud walls, in imitation of the mud cabins in Ireland, and some parts of this country. These houses are very warm, and if they were built with hollow walls they would be still warmer. My mode of procedure will be as follows:—Having procured a quantity of strong clay, which will be worked to the consistancy of mortar, and also liberally intermixed with chopped straw or refuse hay to bind together, I shall place down planks fifteen inches apart in the direction of the walls, and then fill in between them with the clay, making it as firm as possible. As soon as the first layer is dry—for it should not be more than six or eight inches deep—I shall proceed with another one, and so on until the walls are of the requisite height. When the walls are dry they may be plastered over with clay and cowdung, just to give them a uniform appearance. These pits I expect will stand for years, and answer admirably.

Reserve Garden.—Prepare a piece of ground for sowing a general collection of hardy annuals, which in late situations may be sown immediately, but in favourable soils the middle of September will be soon enough. Wallflowers, where they are too thick, must be pricked out into nursery beds for transplanting when the borders are cleared for the winter.

General Tom Thumb Pelargonium.—In answer to numerous inquiries, I may state that plants of this kind are not at my disposal, but in the spring will be plentifully supplied by the nurserymen.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Polyanthus.—Now will be a good time to get in fresh varieties, so that they may get well established before winter. If plants come from a distance, and are planted on the border, a hand glass should be placed over them, and carefully shaded. Loam and leaf-soil, in equal parts, will be found a simple and good compost to grow them in. In the "Florist Reformer" of last week, I see a fine Polyanthus raised by the late John Hufton is omitted; it was let out only partially in his own neighbourhood, and I believe it has not yet been honoured with an *alias*. The sort we allude to is Squire Ray. *Carnations.*—Attend to the directions given last week; and carefully extract all decayed petals from the calyx where there is any chance of seed. Prepare soil to pot layers in, when they are ready to take off. It should be loam, river-sand, and decayed leaves, well turned and thoroughly examined, and run through the hand, so that no wire-worm or grub may escape. The flower-stalks, where there is no seed, may now be cut off close to the surface, and the sticks or supports removed, cleaned, and put away till next season. *Pansies.*—Planting beds for blooming next season ought not to be delayed much longer; we have found the following compost to be excellent, in securing strong healthy plants and fine blooms:—Two parts fresh maiden loam, one part decayed cow-manure, one part street-sweepings, one part leaf soil or decayed vegetable matter. This, if well mixed and sweetened by repeated turnings, previous to forming the bed, will we are confident not disappoint the Amateur's expectations. Turn over the soil of the Tulip bed, and if fresh compost is required, see to it in time.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Where the autumn arrangement of the plants has not taken place, it is time it was set about, as the less they are disturbed after this time the better. The plants in fruit, those for fruiting next spring, and the later successions should, if possible, be arranged in separate pits, as the treatment required by each differs. The plants for fruiting next year, as well as those in fruit, will require to have slight fires made in dull cold weather; let the fires be made in the morning, so as to admit of a little air being given every day. Keep a less humid atmosphere for the spring fruiters from this time, as it is more desirable now to give strength and firmness to the plants, or I may say to thicken the sap of the plants, than to cause them to increase in size. Suckers and crowns that are rooted should have air admitted daily, to prevent their drawing up weakly.

Vineries.—Continue the attention recommended in former Calendars, for the preservation of ripe Grapes from the effects of damp. If wasps are troublesome, it will be found useful to have some thin bunting stretched over the spaces left open for ventilating: woollen netting, such as is used for wall-trees in the spring, is a good material, if the meshes are sufficiently small. All long growths or Vines (whether bearing or not) should now be stopped, as it is too late for Vines to be much benefited by foliage made after this time. Continue to stop all laterals as they are produced; but with late Vines still growing vigorously, care must be taken not to shorten them too much at once.

Peaches.—Let those trees that have shed their foliage have a thorough washing with clean water, to free them from cobwebs and dust, and after this a washing with soap-suds, to check the increase of any of the Coccus tribe which may be upon the young wood, till the trees get their winter-dressing.

Figs.—Continue to pay strict attention to the state of the atmosphere where there are still Figs ripening and swelling, making slight fires in dull cold weather to assist in ripening the fruit; but little syringing and watering will from this time be required.

Melons.—Continue to pay attention to the stopping, thinning, &c. If we have fine weather very good fruit may yet be ripened; keep up a brisk heat by means of fire or linings, in order to admit of plenty of air being given.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Raspberries.—As soon as the fruit is gathered, clear away all the old wood, and any extra shoots left at the summer thinning. Tie the young shoots to stakes or rails, and if very long pinch off their points, but do not shorten them too much now, as from the exposure of the pith, a severe winter would be apt to make the canes shorter than you would wish to have them at spring pruning. Fork in a coating of manure, for, like the Vine, the Raspberry delights in rich feeding. If the above course is adopted, you will be rewarded with well-ripened prominent buds for next season. *Vines.*—Attend to the directions previously given; thin out all useless shoots, remove leaves where they are too thick, and where you do not want the buds in their axils for next season; but while exposing the bunches to more light, be careful to leave a sufficiency of leaves to shade them from the direct influence of the sun's rays. *Gooseberries and Currants.*—A number of bushes protected by netting might now be inclosed in mats, or any other dense substance, for preserving them longer. One advantage of covering some now is, that the buds will be well ripened for next season. The best method I have seen for this purpose was that adopted by the late Mr. Phillips, gardener, at Fingarth. A round frame (large enough to be set over a bush) was surrounded with waterproof gauze, or bunting, and the top furnished with a moveable lid of zinc or tin. Some gardeners very economically preserve Currants until after Christmas, by surrounding the bushes with the straw ropes they had used for protecting their Peaches, &c. in spring. The difference in the appearance of bushes properly pruned in summer, and those that were neglected, is now very striking. Does any correspondent know of a Gooseberry, as well flavoured, and a week or two later than the old Warrington? Keen's Seedling is a fine fruit, but there are plenty of others fit for the table when it is in condition. At present the Warrington stands alone. *Fruit-room.*—Get this in good order for the reception of fruit, and gather not only the finer wall-fruit as it ripens, but also portions of favourite Apples and Pears, so that by sweating part of them by dry sweet hay, you will be enabled to prolong their season.

Routine.—Attend to Mushroom beds in a bearing state, and continue to make fresh ones. Sow Cauliflower for the spring crop, Radishes for autumn and early winter, and a good breadth of Lettuces. The latter, if sown now or a fortnight hence, in an open, airy space, will often stand the weather better than stronger plants growing in more fortunate protected situations. Dig all vacant ground. Continue planting out winter stuff. Hoe, fork, and dig among advancing crops, and give an appearance of thought and system to everything under your management.—*R. F.*

VII.—COTTAGERS' GARDENS.

About this season little is required to be done beyond the ordinary routine of keeping the garden neat and clean. Con-

time to remove all decayed stems and flowers from plants in the flower border, and clear away all vegetables that are no longer useful, so that the ground may be put into proper condition for the reception of other crops. Onions sown about the end of February, or beginning of March, will now be in a fit state for taking up; and advantage should be taken of this fine weather for drawing the bulbs out of the ground, and spreading them over the beds. They should be laid with their roots upwards, and in the course of a few good sunny days they will become sufficiently dry and matured for keeping good during winter. Care must, however, be taken not to bruise the bulbs in pulling them out of the ground, or in handling them at any time afterwards. They should be turned at intervals until they are perfectly dry and fit for removal, when they may be deprived of their roots and the greater portion of their leaves, and placed in some dry airy situation where they can be attended to and turned over occasionally, always picking out those that are in any way damaged to be used first. Many cottagers string their Onions, which is an excellent mode of preserving them. Gather any Apples or Pears that are *ripe*, and go over Vines regularly, stopping them, and *removing* all useless growths, and particularly any that are *formed* above the fruit, which is generally abundant this season, and should be well attended to. Thin out all small berries from the bunches, and keep the branches neatly fastened in.—*J. McH.*

State of the Weather near London for the week ending Aug. 29, 1844, as observed at the Horticultural Garden, Chiswick.

Notices to Correspondents.

FUCHSIAS.—*Clericus.*—It is, we fear, now too late to hybridise these plants, because the fruit will scarcely ripen unless the plants are brought into a greenhouse. Ricartonia is a better female than male, because of its hardiness, while fulgens is tender, and should only be employed as a male. We should try to cross exoniensis with Chandleri, Venus Victrix, or plants of that class, which we should also endeavour to improve by crossing the white and violet sorts with each other. *F. gracilis* would be a good male parent for Venus Victrix. There is no printed guide to these things. We trust to communicate useful information on the subject from time to time. In the mean while, hybridisers should keep very exact records of what they do, and report the result, be it what it may.——*G. H. N.*—Thompson's *F. formosa elegans*, Exoniensis, Eppe's Kentish Bride, Venus Victrix, Youell's Queen Victoria, and Hailey's Sanguinea.*

GENTIANELLA.—*Q.*—Sow the seeds of this as soon as they are ripe (otherwise they soon lose the power of vegetation), in pans filled with rather heavy peat. Sow on the surface, without any covering except a slight sprinkling of silver sand; then place the pans either in a cold frame facing the north and kept close, or on the north side of a wall, where they are completely screened from the sun, and cover them with a handglass.¶

GLAZING.—*H. T.*—Probably your greenhouse roof is too flat; in that case no glazing will prevent the rain coming through, unless the laps are puttied; and if that is done you will still be annoyed by drip. Unless this explains your difficulty, it is not likely that the cause can be determined without actual inspection. The mildew on your leaves apparently arises from damp, or insufficient ventilation.

GLOXINIA TUBIFLORA.—*R. H.*—We never before heard of the flowers of this plant dying off. If you have bloomed five plants, and all, more or less, have died off, and always the top flowers, you have been unusually unfortunate. Perhaps you keep it too damp.

GRAPES.—*M. H. W.*—When Grapes ripen in the open air, they are always well coloured, with a copious bloom. The circumstance, therefore, of your Black Hamburgh Grapes in your house being almost without colour and bloom, although the bunches weigh from 3 to 4 lbs., must be owing to the want of a sufficient circulation of air. In your new Vine-border you may use all the manures you mention, namely, cow-dung, stable do., pigs' do., pigeons' do., leaf-mould, guano, and, though last, the most important, bone-dust; provided you thoroughly mix the whole with the soil by several turnings over.‡

HEATING.—*H. W.*—A very small boiler, say a second size, is large enough. Heat it by tanks by all means, because of their dampness. If you can manage to use open tanks in a chamber below the bed you will be able to steam your house at pleasure, by opening ventilators in the sides of the chamber. No self-acting ventilators answer the purpose in hothouses. The dampness of the air soon puts them out of order. Besides, if you want much ventilation, such contrivances will not give it; if you want very little you may dispense with it wholly. It is a good plan to bring cold air into the house through a pierced pipe; but you had better carry it into the house in such a way as to get the air warmed before it mixes with the plants. Could you not carry it through the chamber of your bed before the air is discharged into the house? You do not want to introduce cold air into either stove or greenhouse, it is fresh air that is required.

HENBANE.—*M.*—This loves deep sandy land. It should be sown at Midsummer or a little later. It is fit for gathering when in full growth the following year, while in flower and before it becomes at all yellow. Then it must be dried gradually in the shade. The seeds are the most active part.

INSECTS.—*R. B.*'s insects are the common cockroaches. The best mode of reducing their numbers is to keep a hedgehog in the infested apartment. *R.*——*R. T.*—We are much obliged. The aphis inhabiting the roots of the Lettuce is the Eriosoma lactucæ. *R.*——*G. L.*—Your spider's web is very remarkable, and we presume it was found in a wall which the ants frequented. We shall feel obliged by your giving us the particulars, and sending one of the spiders. You are aware that what are called ants' eggs are the cocoons. *R.*——*W. R.*—The Elder-tree is infested with plant-lice called Aphis sambuci, which appeared early on the Elder-shoots this season. *R.*——*J. Wigston.*—The curious insects taken from the wasp's nest are females of a beetle called Stylopsis paradoxa, figured and described in Curtis's Brit. Ent., fol. and pl. 19, 2d edit., where you will also find their history; and at fol. 198, that of a parasite named Anoplotrix vespæarum. *R.*——*B. Chilo.*—Your grub is probably the caterpillar of Noctua meticulosa; but you should have said what it fed upon, that we might rear it, and ascertain the species. *R.*——*M. C.*—The little scarlet insects are the Acarus autumnalis; they inhabit Grass fields, Kidney Beans, &c., and are very troublesome in August and September by causing little tumours in the legs, with insufferable irritation. *R.*

LOCAL HORTICULTURAL SOCIETIES.—We learn that the statement that the Eltham Horticultural Society was dead arose from an error of the press, our correspondent, "F. H. S.," having written Eltham, a place between Canterbury and Folkstone. "F. H. S." much regrets that this should have given pain to the lady who acts as secretary at Eltham.

MANURE.—*Experimentalist.*—We are obliged to make it a rule not to recommend tradesmen, unless there should be some urgent necessity, and must therefore refer you to our advertising columns. Humphreys's compound is nitrate of ammonia, with a minute quantity of phosphoric acid, as has been lately shown in former Numbers of this Paper, to which we must refer you. Liquid guano may be given advantageously to all kinds of flowers, provided the dose is not too large. Roses can hardly be over-dosed with it; herbaceous plants may be, because it will make them run to leaf if there is too much of it. The rule for applying liquid manures of all sorts is to do it when plants are growing, and in small quantities frequently repeated. To apply manure when plants are not growing is to waste it. No doubt your fruit trees would be improved by the addition of any sort of manure. Is not their soil too dry? If the Mulberry does not ripen its fruit, you must have a very bad climate, or a very cold bottom, and we can suggest no remedy for those difficulties.——*Suburban.*—Our observations were applied to manure and not to heating apparatus. When stable-litter is heaped over Sea-kale it does not act as a manure, but as a heating material.——*A Constant Subscriber.*—Nitrate of ammonia is a very powerful agent, and must be used with caution, or it will kill plants instead of curing them. The best way of applying it seems to be to dissolve about a teaspoonful, or even less, in a common watering-pot full of water.

MORPHOLOGY.—*W. V.*—Your Cucumber is only an instance of a leaf accidentally growing to the side of the fruit. It does not arise from any breaking up of the system. Such cases are not unusual.

NAMES OF FRUIT.—*L. P. F.*—No. 1. Alfriston; 2. Kerry Pippin; 3. Keswick Codlin; 5. Downton; 7. Bedfordshire Foundling; 8. Scarlet Nonpareil; 10. Margil; 11. Court of Wick.‖——*Miss S. S.*—No. 1. Alexander; 2. Golden Pippin; 4. Nonsuch; 5. Hollandbury. The Plum No. 6 does not appear to be any of the grafted varieties; it resembles the Wine-sour.‖

NAMES OF PLANTS.—*R. G.*—Warrea tricolor.——*H. P.*—Your plant is Portulaca splendens. It shows you how much the Linnæan System is liable to exceptions. The species of Portulaca vary greatly in the number of their stamens.——*B. T. S.*—No. 1. Lepidium campestre; 2. Thlaspi arvense; 3. Rubia peregrina.§——*P. J. O.*—Apparently Fuchsia Thompsonii.*——*B. B. C.*—We assure you that Grasses cannot be named unless in flower.——*Eltham.*—Not a plant, but Oak-spangles, which are described at p. 52, vol. 1843.‡——*F. F.*—Your Fungus is a smooth state of the Scleroderma vulgare, resembling very much Scleroderma geaster, a species which has not yet been found in Great Britain. Smooth specimens of Scleroderma are often confounded with the White Truffle, and in Belgium, where they abound, are collected and sent to Paris, where they are substituted for the real Perigord Truffle, greatly to the annoyance of the *bon vivants*, who complain that the Perigord pies are not what they used to be. *M. J. B.*——*W. D.*—Zephyranthes Atamasco.

PEACHES AND NECTARINES.—*M. D.*—The excessively dry weather, together with the very severe attacks of the red spider, has, in many instances, occasioned the premature dropping of these fruits.‖

PELARGONIUMS.—*An Amateur.*—The following sorts will improve your collection:—Beck's Susanna, Garth's Witch, Pulchellum, Sultana, Foster's Sunshine, and Sir R. Peel. We are not aware to whom the Pelargonium named Fair Rosamond belonged; probably the advertisements will soon make it known.*

REMOVAL OF ROSES AND ORNAMENTAL SHRUBS.—*D—t.*—These cannot be removed by a tenant quitting, unless he is a gardener. *W.*

SULPHATE OF IRON.—*Anon.*—Sulphuric acid will fix ammonia perfectly, and if that is all your object there is no use in employing sulphate of iron. The object of employing the latter is to sweeten manure, partly by fixing ammonia, and otherwise by decomposing the intolerably offensive sulphuretted hydrogen. We presume rather more than twice as much sulphate of iron as sulphuric acid will be required.——*A Constant Reader.*—This dissolves readily in cold water. If to be added to putrid fluids, it may be dissolved in just as much water as it requires and no more. But if it has to be applied to solid masses, then it should be largely diluted, or it will be wasted; say in the latter case ¼ lb. to a gallon of water. It is not probable that any animals would lap it up, because of its unpleasant taste; but it is as well not to leave it about. In small quantity it is hardly a poison.

TULIPS.—*B—k—g.*—Refer to No. 24 of the *Gardeners' Chronicle* for the present year, p. 398, and you will find the information you seek about Tulips. Change of soil and situation afford the best chance for breaking them.*

UNDERWOOD.—*H. W.*—The best description of shrubs to be placed in a plantation of large trees to fill up the blank appearance of the ground, is Privet, Holly, Common Laurel, Blackthorn, Buckthorn, Yew, and Furze, or Broom.

VINES.—*Clericus.*—Follow Mr. Roberts's advice. If you get them forward before planting them out in March, you must be very careful to mulch the ground all round their roots with plenty of warm stable litter. The grand thing this year is to get the wood thoroughly ripe, and that can only be done by keeping them in a hot, dry, airy situation until the wood is hard.*

YELLOW PICOTEES.—*B—k—g.*—Procure the following sorts:—Barraud's Favourite, Euphemia, Wilson's Isabella, Willmer's Romulus, Rajah Ramahun Roy, Khouli Khan, Charles X., Brocks' Prince of Wales, Queen, Mars, Lady Chetwynde, Countess Ashburnham. Save your own seed.*

MISCELLANEOUS.—*A. E. D.*—We cannot name your Gesneras by description. Anicia zygomeris is an odd-looking, rather handsome yellow-flowered papilionaceous plant. Tremandra Hugelii is a pretty greenhouse bush; Drymonia punctata is a curious stove trailer, with the habit of a Columnea.——*A Subscriber.*—The Isle of Wight, like all islands, is much warmer than the mainland, and is also sheltered by it; and then its coast lies high and dry; both which circumstances sufficiently account for the mildness of its winters. Arbutus seed may be obtained from old trees in this country; Bay and Myrtle-seeds from Italy. All such things are troublesome to procure, because they are not common articles of trade. We regret our inability to assist you. If they come into the market, any nurseryman will know how to obtain them.——*Orbelana.*—Peucedanum Sowa likes a fresh, loamy soil, dry in winter and damp while it is growing. Silene maritima is growing luxuriantly in a stiff, loamy soil, just before our windows. Winter Savory is Satureia montana.——*P. J.*—Of course they will be advertised.——*Dianthophilus.*—Neither of the specimens you have sent is the true *Clove* Pink of our gardens; they are not the true colour, nor do they possess the delicious spicy fragrance of this old favourite, which is of a rich red maroon colour. Your biscuits are purple, and nearly scentless.*——*A Novice.*—Your Fuchsias, lately removed to the open ground, that are becoming sick, and whose leaves are turning brown, have not been sufficiently supplied with water. Fuchsias are thirsty plants, and should be well attended to in this respect, or they very soon lose their leaves.——*Glerioses.*—The chief thing to be attended to in plants for winter or early spring flowering, is to get the wood thoroughly ripened. After that they may be introduced into heat at any time. Pelargoniums cut down in June last may be made to flower next February or March, if they are forced.‡——*C. M.*—In striking cuttings of Fuchsias, at this season of the year, it is advisable to place them on a slight hotbed.‖——*W. C.*—To your conservatory climbers you may add Ceanothus azureus, blue; and Passiflora Loudoni, crimson.‡——*B.*—Rhododendron lapponicum, chamæcistus, and chrysanthum, are among the very rarest plants. By all means preserve them in pots during the ensuing winter in a cold pit, which you can keep free from too much damp. Place them near the light, and give them air whenever you are able.——*A Reader.*—Much information respecting Vegetable Ivory is given at p. 836, vol. 1843.‡——*A Subscriber.*—The directions respecting the preparation of ground for Asparagus, given at p. 844, are good; but by adding a little more manure, if you have plenty of it, the plants will grow all the better, provided you do not put it too thick, as in that case it is apt to become soddened and rot the plants.‡——*A Beginner.*—Strawberry-plants for forcing, when taken from the striking-pots (60s.), are generally shifted into 32s. We do not consider that they would do better for having an intermediate shifting into 48s. There is no better way of destroying green-fly in a Cucumber-frame than smoking them with Tobacco, provided the operation is rightly performed. It should be done when the leaves are dry.‡——*B. F.*—It is published in time, for the morning mails.——*Amicus.*—Messrs. Lane and Son, Berkhampstead.

SEEDLING FLOWERS.

CARNATIONS AND PICOTEES.—*P. C.*—20, a bizarre Picotee, with yellow ground; the flower is large and full, with a good crown, and large guard petals; but the edges of the petals want smoothness, and the colour is too much distributed over the surface of the petals; it is a good border variety. Of the two lemon-coloured *selfs*, 12 is decidedly the better of the two, the petals being larger and stouter than in 13; but seedlings like these are very common.*

DAHLIAS.—*J. B. R.*—Your seedling is of a good colour, but the petals unfold irregularly; the centre is also confused and deficient in petals; it shows the yellow disk.*——*W. A.*—Your *Islington Rival* is a very promising specimen; the arrangement of the petals, their form and substance, are good, and the eye is well elevated; it is a compact and finely-formed flower; colour, deep maroon.*——*T. R.*—The bloom of your white Dahlia had broken short off, and was much bruised and damaged. The petals are of a good form, and well arranged, and the flower is of a good general form; the centre in the bloom sent was imperfect, and we fear this part of the flower will prove too thin.*

FUCHSIAS.—*J. W., Pittenzie.*—Your seedling No. 1 is an elegant flower, of good texture, and though wanting the violet colour in the corolla, it still makes a pleasing variety.*——*J. H. C.*—The form of the bud of No. 39 is curious, being so perfectly globular; but it possesses no other qualification to recommend it to general cultivation. 54—Tube and sepals bright carmine, smooth and shining, but the corolla wants colour, and it is no improvement upon globosa major. 83—Not sufficiently compact, and deficient in colour. 99 very much resembles Venus Victrix, but not equal to that variety, from the corolla possessing less of the violet colour, and the tube and sepals not being so light. 64 is very pretty, and singular in appearance, from the corolla being of a very peculiar colour (a dove colour), with delicate pink tube and sepals, tipped with green; an elegant little flower.*——*R. and S.*—Your seedling 1-44 is a showy and desirable variety; the tube and sepals are of a light delicate flesh tint—the latter with green tips; corolla rosy vermilion; flower-stalks long; the largest of its colour we have seen.*——*Y. Z.*—Your seedlings are very good flowers—fine in texture and good in colour. The violet purple corolla in No. 1 forms an excellent contrast with its bright carmine tube and sepals; this is a large and elegant flower. 2 is also a large and fine flower, with less violet in the corolla. Next to this we place 7, as the colours are more brilliant, and the form more graceful than 8, which is rather a stouter and larger flower; in the two latter specimens there is not so strong a contrast in the colours, and they much resemble each other. 6 is an elegant flower, with a fine violet corolla, but not superior to some of the older sorts in cultivation; the same observation applies to No. 4.*——*W. D. B.*—The seedling from fulgens which you have sent is a very handsome variety; the bunches are large, the one sent containing more than 60 flowers, the tube of which is slender, of a delicate flesh colour, with pale-green sepals; the corolla is of a bright vermilion, seen in the spaces between.*——*Clericus.*—Your Fuchsia is a very good flower, rich in colour, and of a good shape; it, however, wants novelty, and there is nothing sufficiently distinct from other varieties to render it preferable to them for general cultivation.*——*J. H.*—Your seedling in form is better than those we are in the habit generally of seeing, it is also good in colour and moderate in size; it, however, bears too strong a resemblance in its general appearance to some of the sorts lately introduced, particularly in its want of violet in the corolla; nevertheless, if the habit be good it is worth growing, being a finely-proportioned flower.*

LOBELIA FULGENS.—*F. B.*—Both your seedlings are very handsome varieties, particularly *L. fulgens multiflora*, the lip of which is large and broad, of a rich and dazzling scarlet. *Fulgens pyramidalis* is also a fine variety; not so large as the former, but of the same brilliant scarlet. They are both very desirable flowers.*

MIMULUS.—*J. W. E.*—Your seedlings do not differ from other varieties we have seen; the orange, No. 7, and the scarlet, No. 6, are the best; the other colours are what we generally see in all collections raised from seed.*

PANSIES.—*W. H. M.*—Your seedlings are inferior to sorts similar in character; 1 is too long in form, and 2 is poor in colour.*

PETUNIA.—*X. Y. Z.*—Your seedling reached us in such bad condition, that the shaded appearance to which you allude could not be perceived.*

PELARGONIUMS.—*J. C.*—Your specimen wants both size and substance.*

PHLOX DRUMMONDII.—*S. G.*—The two specimens sent—seedlings from your variety named *splendens*—are fine in colour, and the lighter variety is good in form also.*

VERBENAS.—*Z. C.*—Neither of your seedlings appear to be new or striking; the rose-coloured variety is very pretty in colour, but rather deeply indented, and the divisions curl about, which gives it a confused appearance; the light variety wants novelty.*——*S. G.*—The best seedling in your collection is one named *Rose d'Amour*; this is distinct in colour, being of a bright and lovely pink colour; a large and good flower. *The Lovely Rambler*, light lilac with pink eye, is also a good flower. *Messenger*, a good lilac, too much resembles some of the older varieties. *The Giant*, a light lilac with dark eye; the head of the flower is large, but the colour wants clearness; and *Mulberry*, though a good flower, is surpassed by others in cultivation. *Belvoirii* and also *Intensiva* are not worth cultivation, in the present improved state of this flower.*

ERRATUM.—In Mr. Miller's advertisement of Seedling Geraniums, inserted 24th August, the price should be 5s. for 40 seeds, and not 6s.

SEED-WHEAT.—Any one desirous of obtaining Seed-Wheat for use this autumn, may ascertain, by application to me, the particulars of the crops of two excellent varieties—Shirreff's Hopetoun, and Morton's Red-Straw White, which have been grown on
WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE, during the last 3 years. This year's crop is on sale at 8s. a bushel.—JOHN MORTON, Whitfield.

The Agricultural Gazette.

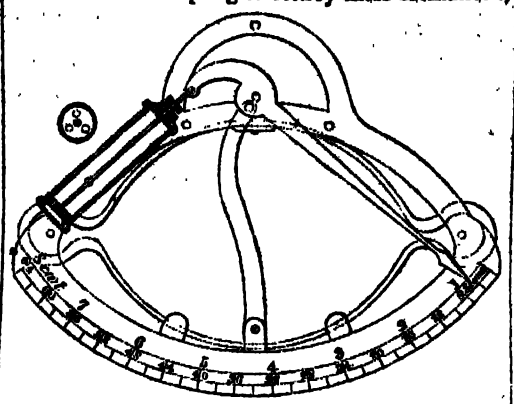
SATURDAY, AUGUST 31, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

TUESDAY, Sept. 3 [Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

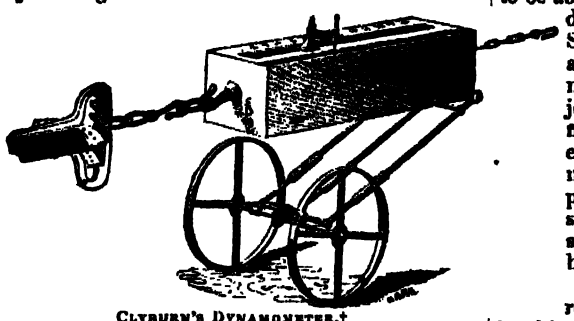
Sept. 3 Ush. | Sept. 10 Aberguveny.



THE ECONOMICAL VALUE OF ANY FARM IMPLEMENT—if, for the moment, we disregard its cost price—depends, first, upon its efficiency—*i. e.*, the degree in which its work approaches perfection; and secondly, upon the expense connected with its use—*i. e.*, the horse-power and manual labour required in working it. There are thus two subjects of inquiry connected with every machine, viz., its construction, first, as affecting its efficiency, and secondly, as affecting the power required to work it.

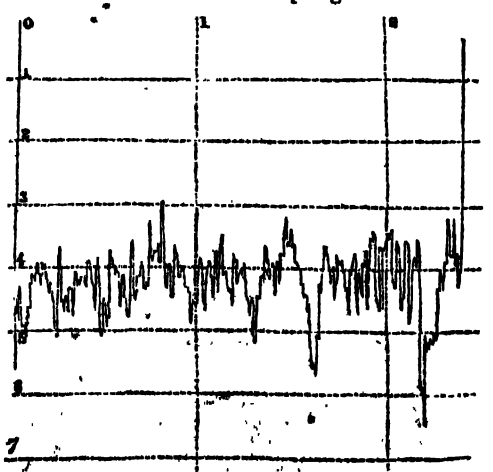
Let us take up the consideration of a particular class of implements; the first to which our attention is naturally due are those of cultivation. All these, including draining-ploughs, subsoil-ploughs, common ploughs, harrows, scarifiers, grubbers and horse-hoes, rollers and clod-crushers, admit of this two-fold consideration, and require it in order that their real value or usefulness to the farmer may be fairly estimated. There are a great many forms of all these implements: that is the best of each, in which excellence of work and lightness of draught are united in the most profitable proportion.

In estimating the efficiency of the different implements which claim our notice, we shall have to consider the object for which they are used, and how far they are respectively successful in effecting it. This will be better done when we come to describe them each in its turn. At present, we may make a few remarks on the other subject, which we have said affects machines generally—that of draught, and on our present means of measuring it in farm implements.



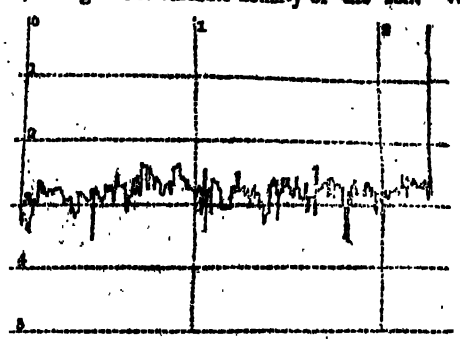
The first AGRICULTURAL DYNAMOMETER, and till lately, we believe, the only one in use, consisted simply of an elliptic spring; and the degree in which this spring collapsed, on being pulled asunder lengthwise, was taken as an index of the strain to which it had been subjected. One of the sides of the ellipse being fastened to a metallic plate, on which the spring lies, its collapse, on subjecting it to a longitudinal strain, (as, for instance, by making it a link in the draught-chain of a plough,) causes the other side to approach it, and this motion is communicated by means of rack-work and pinion, or by a compound leverage, to a radial index on the other face of the metallic plate, where a circular scale, to which this index points, has been divided, by previous trials, into cwts. and stones. The position of the index on the scale is thus indicative of the amount of longitudinal strain to which the spring may be subjected. If it be attached to a plough, the effort of the horses in drawing the implement through the ground will be exhibited by the position of this index; for when the strain is greatest, as where the ground is hard, it will, owing to the greater collapse of the spring, point to a greater number of cwts. and stones as the measure of the horse's exertion, than when the soil being loose the implement is more easily pulled through it. This instrument has been a good deal used in determining the draught of ploughs, but with little service, owing to the extreme variability of the strain which it is here required to measure. The density of soil, as the plough is drawn through it, is so rapidly and incessantly variable, that so far from being able to judge of the average draught from watching the rapidly-oscillating index of this dynamometer, the operator is unable to state at any one time what the position of the index actually is. In order to remedy this defect in this instrument, Messrs. Cottam and Hallen, of Winsley street, London, have contrived a modification of it, of which the following is a figure. A cylinder and piston, represented in section, are here interposed between the two sides of the spring by the same system of levers which work the index, and the motion of the piston is rendered difficult by the cylinder being filled with oil, which must pass through small holes pierced in the piston before the latter can shift its position. A sluggishness is thus imparted to the index, which allows its average position to be more accurately estimated. Still, however, in using this instrument, the operator has to depend a good deal on his own judgment in pronouncing what the draught of the implement under trial is; and this is an imperfection.

Instead of attempting to destroy these oscillations,



COTTAM'S DYNAMOMETER.*

much the better method is to adopt an arrangement by which they may be recorded by pencil on paper, in the same way as in anemometers the variable force of the wind is recorded. Mr. Clyburn, engineer to the Earl of Ducie's iron works at Uley, Gloucestershire, has constructed an instrument on this principle, which is represented as at work in the subjoined figure.



CLYBURN'S DYNAMOMETER.†

The spring in this case is spiral, and the strain which it is intended to measure is made to compress it. The motion of the plough is communicated by means of the wheels, which hang from the instrument and roll on the ground, to a cylinder within the case of the spring, and as this revolves it unwinds and rolls up a strip of paper which is wound on another cylinder close by it, within the same case. This paper is marked as in the following figures, with transverse (vertical) and longitudinal (horizontal) lines, the one corresponding to the positions of the dynamometer's index, under the strains successively of 1, 2, 3, 4, &c. cwts., and the other dividing the paper into sections of a width corresponding to 25 yards of ground passed over, as calculated from the size of the wheels communicating the motion of the plough. As already stated, when the power is applied, the spring is compressed, and this gives motion to a rack and pinion that has a pulley fixed on the same spindle; this pulley has a chain passing round it, which gives motion to a pencil and pointer; the pencil oscillates in a line, parallel to the cylinders just described, and it is kept by a spring pressing upon that cylinder, which, as the plough proceeds, is winding up the strip of paper which we have been describing. The consequence is, that the paper carries off, marked upon it, an irregular line, the position and character of which depends upon and indicates the intensity and irregularity of the strain to which the spring has been subjected. The curious and interesting figures below are reduced (½) from actual drawings by the pencil of this dynamometer when attached to two different ploughs.

They make good our remarks as to the extreme variability of the draught of implements of cultivation, owing to the variable density of the soil. We

do not know of what ploughs these record the draught, nor whether they were working at the same depth in similar soils at the time; but it is evident that they are far more instructive than the most lengthened and detailed description, of the nature and intensity of the effort which the horses made in drawing the implements through the ground.

We see that the draught of the first plough averaged 4¼ cwts., and that of the second not more than 2¾ cwts.; the draught, also, of the first plough is obviously more intensely, but not more rapidly variable than that of the second. We hope hereafter to be able to lay before our readers an Essay on the draught of some of our best English and Scotch ploughs under similar and under variable circumstances—written, not by ourselves, nor by any other experimenter on this subject, but by the unerring pencil of this dynamometer; and we are sure that a simple examination of the paper of Clyburn's dynamometer, after being applied to different ploughs working at various depths in various soils, will be far more interesting and instructive than a detailed description of the trial by a most accurate and attentive observer.

We hope to be able to inform our readers, as we proceed, of the draught taken by this dynamometer of the different machines we describe.

* The price of this instrument is 7*l*. † Price 14*l*.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(Concluded from page 578.)

Marlstone.—Below the sands of the inferior oolite lie a series of beds which, near Dursley, where they are most fully developed, consist of an indurated sand, containing vast numbers of shells. This rock, which receives the name of Marlstone, is generally of a light-brown colour, while the shelly concretions which everywhere pervade it are of a grayish blue. It is exceedingly tough, and is extensively used as building material. Immediately above it, and separating it from the sand of the lower oolite, a very thin bed of clay occurs, containing thin layers of limestone rock, precisely resembling the lias limestone. It frequently is not easily traceable, from being here and there obscured by overlying debris; a very excellent section of it, however, may be observed on descending Frocester Hill, towards Coaley Hamlet; after passing the limestone, and then the sand of the inferior oolite, we there find that they rest on this stratum, averaging 10 or 12 feet in thickness, of a light-coloured clay, in which as many as a dozen courses of a grayish limestone, each not above 3 inches in thickness, occur. This bed is also well seen at Tick's Hill, below Coaley Wood, and at Waterleigh Valley, on the other side of Stinchcombe, in each of which places thin limestone beds are to be seen. It is also seen at Horton Hill, where it is a dark-blue clay; and it is visible at intervals along the foot of the hills between these places. The junction between the marlstone and sand of the lower oolite is easily traced when this bed of clay which separates them is visible. This, however, is not everywhere the case, and, therefore, though at Dursley, where the character of the rock is well developed, boundaries are easily traced, this is not easily done near Bath, where its character is much altered. At Dursley the marlstone forms an extensive terrace, stretching out from the foot of Stinchcombe Hill half a mile into the valley; beyond Wotton-under-Edge, however, and in the southern part of our district near Bath, it does not form so important a member of the oolitic series, being thinner, and losing the indurated and rocky character of the Dursley rock; and as the bed of clay above it there disappears, or is not easily traceable, it is not easy to distinguish it from the sand, which there occupies so considerable a portion of the escarpment. The section at Frocester Hill just noticed, exhibits also the character of the marlstone. It there consists of a series of beds of rock, of the character described above, from three to thirty feet thick, alternating with beds of blue and brown marl, varying from ten to twenty feet in thickness, and comprising in all a thickness of about 100 feet. Not far from this section the bed of clay above the marlstone is of a dark colour, which, many years since, gave rise to the idea of the then proprietor of the land, that, probably, coal was not far off, and trials were accordingly made. A shaft was sunk, which, of course, has been long since filled up, but the mound of the material excavated still remains, a monument of the geological ignorance which then existed.

Agricultural Character of the Marlstone.—The bed of clay above the marlstone is of very little agricultural importance, being of such insignificant extent. In one field—the only arable one in which I know it to be exposed—the soil is full of fossil shells of the ammonite. It is a clayey soil on which good crops of Wheat are raised. Clover seeds with Rye-grass have frequently been tried on it, but, with the exception of one corner of the field, which is lower than the rest, where the marlstone is exposed, they have uniformly failed. The Rye-grass sown along with them, however, grows well. The soil on the marlstone differs from that on the upper lias in being lighter. It is a sandy loam of variable depth, and is wet or dry, according as it overlies the calcareous sandstone or the clayey strata of the rock. When dry it is one of the most fertile descriptions of soil occurring in the district. The general rotation over the Dursley district, where the land is chiefly arable, is one of three years' duration. Wheat is followed by Barley or Beans, and that by seeds or Potatoes; a portion of the land being near the rock, and therefore brashy, is well suited for the growth of Barley. The heavier portions, again, are adapted for the growth of Beans. No Turnips are cultivated in this district. The common field system exists over a great portion of it, and the right which, under this system, certain of the proprietors and occupiers in the several parishes have, of folding their stock over the whole of the unineloscd land during winter, effectually hinders any attempts at Turnip culture. The average of the several crops is as follows:—Wheat per acre, 26 bushels; Beans, 30 bushels; Barley, 30 bushels; Potatoes, 70 sacks. The general seed-time is needlessly late. Barley sowing, for instance, rarely commences till the month of May; the period of harvest is consequently late. Wheat is generally harvested by the end of September. Beans by the middle of October; and it is thought sufficiently early if the Potatoes be housed by the time of Dursley Fair, which occurs on the 4th of December.—*M.S.*

ON FLAX SEED AS FOOD.

In a series of Papers which have already appeared in previous Numbers of the *Agricultural Gazette*, the cultivation and management of Flax have been minutely described; but as the application of the seed on the farm has lately attracted much attention in several districts in England, it has been suggested to me that it would be desirable to place that subject more prominently before the public than I have already done. With a view of procuring further information in this new and important department of husbandry, I have lately, in a visit to certain parts of the eastern counties, where attention has first been prominently directed to it, had an opportunity of seeing Flax-seed extensively and efficiently employed for this purpose, and the results of this it is my present purpose to place before the readers of this Journal.

The practice described in the Papers referred to in the preceding paragraph is that recently introduced into Ireland by the Belfast Flax Improvement Society, and it will be seen from a perusal of them, that the production of fibre is there regarded as the especial purpose for which the crop is cultivated, the seed being entirely a secondary consideration. In the majority of cases, indeed, so little importance has hitherto been attached to the seed that it has been entirely disregarded, partly from the circumstance of its value not being understood, and partly, also, from an erroneous opinion being entertained that the saving of the seed would be injurious to the fibre. Under these circumstances it will be perceived that the full value of the crop was not taken advantage of, and from the returns thus obtained no just estimate of the value of the Flax plant could be formed. This will be more apparent when it is considered that in circumstances unfavourable to the production of fibre an extra quantity of seed will be obtained, and *vice versâ*. Properly speaking, therefore, where advantage is taken of both products a failure can rarely be experienced, although where only one or the other is regarded, such an occurrence may be expected occasionally to take place. Where the fibre only is the object of cultivation this is more especially the case; and this circumstance caused the extent of land appropriated to the growth of Flax in Ireland to become annually less, so that without the intervention of the vigorous measures resorted to by the Belfast Flax Improvement Society, the cultivation of Flax, one of the staple productions of Ireland, would soon have been known only in name.

The defective management so long practised in Ireland resulted chiefly from ignorance as to the value of the seed apart from its application for the purpose of reproduction. Until lately, the husbandry of that country was wretchedly defective in every particular. The domestic animals were for the most part dependent for food on the spontaneous productions of the earth, little attention being paid to the growth of green crops. Under these circumstances it may be supposed that the use of oil-cake was entirely unknown. In this country, however, where improvements in cultivation scarcely kept pace with those effected in the rearing and feeding of the domestic animals, oil-cake has long been extensively used, and justly esteemed as a rich and nutritious article of food; and the Flax-plant not being generally cultivated here, large importations of that article annually took place. The oil-cake is well known to be the refuse of the Flax-seed after the oil has been expressed; the money-value of these ingredients being nearly in the proportion of one to four in favour of the latter. The value of the seed as an article of food before expression is therefore apparent; and it is not a little singular that it should have hitherto been so little employed for this purpose.

It is a curious coincidence that while exertions were being made in Ireland for the improvement of the growth of Flax, having reference chiefly to the production of fibre, attention was in this country directed to its cultivation for the production of seed, the fibre being disregarded, or at all events being a secondary consideration. Indeed, the returns obtained by Mr. Warnes, of Norfolk, from the seed alone, are much greater than those usually realised in Ireland from the fibre; and that gentleman has satisfactorily shown that without taking the value of the fibre into consideration at all, the Flax plant could successfully compete with other cultivated crops. The latter is, however, too valuable to be disregarded in any case, as, how ever inferior in quality it may be, it can still be profitably disposed of to the manufacturer.

Flax is usually regarded as a highly exhausting crop; and this opinion, has, in many cases, retarded the extension of its culture, even where the returns obtained from it were sufficiently remunerating. That it is in a greater or less degree an exhauster of the soil must be admitted; and this quality may be supposed to be increased by allowing the seed to ripen fully before taking up the crop; but the consumption of the seed on the farm will alter the character of the crop in this respect, and render it restorative instead of exhausting.

The process of saving the seed has been already described at length, and need not again be further adverted to, the present paper merely relating to its application as an article of food. It is perhaps unnecessary to apprise the reader that this subject was first prominently brought before farmers by Mr. Warnes; and after a perusal of the statements and experiments in the sequel it will be seen that he has laid his countrymen under very considerable obligations for his exertions. Having ascertained the advantages to be derived from the system, he persevered in advocating its extension until a society was organised in Norfolk for the purpose, which at present has numerous auxiliaries in connexion with it in Norfolk and Suffolk; and considering that the culture of Flax was previously unknown in that part of the country, and that the management to be adopted in almost every stage of it is very different from the usual farming operations, it must be regarded as not a little extraordinary that the extension of the crop has proceeded with undeviating regularity, and that fields of several acres may be frequently seen throughout the districts over which the influence of these societies extends. Although the seed is there the principal object, the preparation of the fibre has not been forgotten. In this respect, the example of the Belfast Society has been imitated, the services of Belgian and Irish operatives having been secured to teach the different processes of the manufacture.

Flax-seed has been found to be equally suited to the different animals of the farm, for all of which it is a nutritive and valuable article of food. It is not available for this purpose in its natural state, as, if given whole, it would pass through the animals almost unchanged; nor can it in any case be given in large quantities, for then the effect of it would be at once to subject the animals to violent purging. It is also necessary that it should be combined with other matters of a less nutritive character, in accordance with the established fact in the animal economy, that the ingredients necessary for the support of life are not advantageously used in a highly concentrated form, and that quantity no less than quality must be regarded. The Flax-seed is ground into meal, and at once combined with the other ingredients, the whole being afterwards boiled or steamed, or it is boiled alone with water, and then merely mixed with the other matters.

The indirect advantages obtained by the consumption of Flax-seed on the farm are various. It is well known that the chief difficulties to be contended with on the heavier class of soils—and these constitute a very considerable portion of the surface of the country—is the production of a sufficient supply of nutritious or green food to be consumed with the refuse grain and hay and straw; but this difficulty may in a great measure be removed by the use of Flax-seed. It will render any mixture of these, however coarse, sufficiently nutritious, not only for feeding, but for fattening. Though adapted to a wide range of soil, Flax is best suited to those of the heavier class, and it is on these also that the production of green food is the greatest desideratum. Great difficulty is usually experienced on such soils in converting the superabundant supply of straw into manure, as no considerable portion of it can be consumed by the domestic animals by itself; by the aid of Flax-seed, however, it may all be converted into nutritious food; and when such combination is extensively used, every exertion will be required to economise the refuse matters for litter, instead of otherwise ineffectually attempting to convert them into manure.

The use of Flax-seed may further be made auxiliary to the extension of the practice of soiling or house-feeding during the summer. The advantages of this system of feeding are well known, as economising the supply of food, by which an increased number of animals can be maintained; and also as greatly adding to the stock of manure, and consequent increase of fertility in the soil. On all the inferior kinds of soils, soiling has hitherto been found impracticable, the natural produce in such cases not being sufficiently nutritious for the maintenance of animals in a state of confinement; but here the aid of Flax-seed may be rendered available, as the jelly produced by boiling it, combined with the coarser Grass, will form a nutritious compound, relished by every species of live stock. It will at once be perceived that the use of Flax-seed will add, among other advantages, in a great degree to the fertility of the soil, by the production of a greatly increased quantity of manure, and that of a very superior quality. In no other respect, perhaps, can it be regarded of more importance than in this, as the increase of the productive powers of the soil should be steadily kept in view.

Premising these general remarks on the subject, it will perhaps be more satisfactory to the reader to detail the management adopted in the use of Flax-seed, with some of the results thereby attained. Here a reference to facts is necessary; and for this purpose I shall describe the system followed at Horkesley Hall, near Colchester, by the Rev. Mr. Blair Warren, to whom I am indebted for many of the statements which follow, which may therefore be implicitly relied on. Though long aware of the value of Flax-seed as an article of food for live stock, I cannot forbear expressing the surprise and great gratification which I experienced in the inspection of the system of feeding at Horkesley, where sheep and other stock are fattened with a proportion of Flax-seed jelly, both in houses and out of doors.—*J. Sproule.*

(To be continued.)

NOTES OF A JOURNEY THROUGH SOUTHERN AND WESTERN ENGLAND.

I do not pretend either thoroughly to know the English farming, or to be capable of entering into a minute investigation of its merits or demerits, for I have spent little more than ten days in the country, and those have been chiefly occupied in travelling on railways and coaches; but there are various points so obvious as to strike the eye of the most cursory observer.

The following remarks have reference to Berkshire, Wilts, Gloucester, Worcester, Stafford, and Cheshire. On leaving London by the Great Western Railway, and proceeding through Middlesex to Reading, we pass through a fine, level, rich country, a considerable extent of which is in crop, principally Wheat, which presents a good appearance, and (August 3d) is mostly ripe; Oats are generally a light crop. To the west of Reading the railway runs through cuttings of chalk, mixed with flint nodules; at the Oxford junction line the soil is poorish, low-lying, and mossy; from that to Chippenham is a fine country, lying chiefly in meadow Grass, subdivided into small fields, surrounded by hedge-rows, ditches, and trees; around Chippenham it is hilly and rather poor, and on to Bristol still hilly; between Bristol and Gloucester is a fine undulating country, still principally in Grass.

I believe I am correct in saying that in the whole of the country named, and on to Birmingham and Liverpool, there is not above one-third in crop, if so much; and the remaining two-thirds are lying in meadow Grass, a portion cut and made Hay, the rest pastured; the modern improvements of draining, soiling cattle, proper rotation of crop, including Turnip, Clover, and Rye-grass, deep ploughing and thoroughly cleaning the land, seem to be anything but generally adopted. When we see the fields laid out into ridges of 2 or 3 yards in breadth, the furrows in many instances being almost bare of crop, how can we account for it but on the supposition of the land being wet? Again, I do not think I exceed the mark when I say, that for every 10 acres of surface there is 1 acre rendered useless—nay, worse than useless, absolutely injurious—by hedge-rows, ditches, and trees; almost every paltry field of 2 or 3 acres must have its hedge and ditch, and in very many instances its row of trees. Did these hedges do no more harm than occupying the ground, they would be bad enough; but they afford shelter and nourishment to all sorts of weeds, insects, and vermin, rendering it almost impossible for the farmer to keep his land clean; untouched, they furnish annually a crop of seed-weeds, blown by the wind through the fields, defying all attempts to keep the land clean; and when the field is in crop, if the season happen to be at all wet, the crop must be lost from the want of a free circulation of air.

When travelling on the Great Western Railway, we heard some people remark, they would rather see the fine green fields of England, with her hedge-rows and trees, that contribute so much to beautify and adorn her, than see nothing but corn fields. Utility, however, before ornament, say we, so long as England cannot grow corn enough to support her inhabitants. While we have the strange anomaly of plenty of capital with a superabundance of labourers, vast numbers of whom are bordering on a state of destitution; when so many of our countrymen, finding it difficult to earn a subsistence at home, are annually emigrating to other countries, and seeking to themselves a home in remote quarters of the globe—it seems strange that so large a portion of the fine and fertile soil of England should remain only half cultivated; that we should assist in exporting our countrymen to reclaim wild land in America and Australia before first properly cultivating our own.

In travelling through these counties one is surprised to see in some parts ploughs (large, clumsy, wooden articles, with two large wheels fixed at the end of the beam) drawn by three or four horses in a line, with a man or boy besides the ploughman driving the horses; and one can hardly restrain a laugh at such a needless waste of animal labour, knowing that two horses will in general do more work yoked abreast to a plough than four yoked before each other in single file, because some of the power of the foremost horses is always wasted in its passage along the sides of the hind horses, and while turning, the hindmost one has the whole draught to bear. In Scotland, and many well-cultivated parts of England,

all ploughing, except perhaps subsoiling, whatever be the land, light or heavy, is performed with but two horses yoked abreast; and with a properly-constructed plough these are found amply sufficient.

Having now run over shortly what I think are the leading defects that struck my notice in my short journey, let me as shortly point to the leading remedies:—First, then, the landlords as a body ought to grant long leases of 19 years at least, and on grain rents, or at so many bushels of grain per acre, at the average price of the county; for what man will invest his capital in improving land, without having a vested right in his improvements? or who would run the risk of spending his means in draining or otherwise improving his farm, with the liability instantly after of being turned adrift at the mere caprice of his landlord? The landlords should also take upon themselves the payment of the whole burdens, whether in the shape of tithes or poor-rates, &c., so that the tenant would have a fixed rent before him, and have nothing to fear—nothing to prevent him laying out his capital to the best advantage. The law of hypothic should also be abolished. This was enacted for the protection of landlords, but it is very questionable if it does not react upon themselves, by preventing the tenant from borrowing money to carry on improvements in the same way as other classes of the community. If a manufacturer, for instance, has 1000*l.* on machinery, he finds little difficulty in borrowing money to the extent of at least half its value; not so the farmer. Who will lend to him, when his landlord has a preferable claim on the property?

The next thing to a proper cultivation of the soil is a sufficient supply of manure; and this cannot be procured without keeping a large stock of cattle, for which in the counties named there is no means of subsistence: to overcome this difficulty it is necessary, instead of as at present having two-thirds nominally in Grass but in reality producing little, to introduce green crops, crops of artificial Grasses, Turnips, and other roots; for it is well known that the same ground which in poor pasture would only feed a few cattle in summer, will, under the crops mentioned, feed three or four times the number all the year round, if they be kept in the house, the food being brought to them: three or four times the quantity of manure will thus be produced. Again, take a farm of 300 acres, only one-third of it being cultivated, the remainder in Grass—how few people are employed here! Change the system, and we have three or four times the number employed. Were this universally adopted where required, and were the land drained and rendered fit for bearing crops, and subsoiled, and thoroughly cleaned and manured; were those useless hedgerows, ditches, and trees, that take up so much ground, and damage so much more, swept away, we should find no redundancy of labour in the market; there would be no anxiety about the unemployed—no talk of exporting the strength and sinew of the country, and no fear, as at present, of annually importing a large quantity of foreign grain.—*A Strathearn Farmer.*

Home Correspondence.

Knap-weed.—Our pastures are nearly covered with a coarse Grass, which they call here knot-weed, and it is this year making its appearance even where they were mown for Hay. Neither cows nor horses eat it. Is it of any use in protecting the more tender Grasses? or is it so injurious, by taking up the room and nourishment of better sorts, as to make it worth while to have it pulled up by hand? Now the ground is wet some of the stalks pull out with a portion of the root; but as many break off it will require pulling several seasons before it can be eradicated. It seems to grow most where the ground has been drained. Would it not pay generally to pull out all the coarse weeds from permanent pasture land?—*J. B.* [Persevere in pulling it up, or cutting it off with the spade; no weed can continue long in the ground if treated thus.]

Protection to Bark of Trees.—Twisted Hay or straw-bands bound round the stems of fruit-trees, and slightly coated with gas-tar, will prevent sheep or cattle injuring them. Painting the bark with any kind of mixture may close up the pores of the outer skin, and thus retard the growth of the tree. By the above plan, the air has free access to the boll.—*Falcon.*

Sowing Corn.—The simplest way of sowing Corn over lea land, is to do it broadcast over the first furrow. The seed in this case will fall between the lips of the furrow, and all the advantages of drilling will be obtained, along with the cheapness and speed of sowing broadcast. It is evident that in this case there will be an advantage in having much earth raised in the form of ribs, between which the seed will lie, as then the seed will be sure to be covered. The greater the quantity of earth thus raised, the more efficient will the covering be when the harrows drag it down; and this appears to be the proper office of the harrow. In some districts heavy drags are used to stir the furrow to the bottom; now this is not the office of the harrow, but that of the cultivator, scarifier, or whatever it may be called, which will do it more effectually, and with less difficulty. The office of the harrow is to drag weeds to the surface, and to reduce clods or any unevenness of surface; and, to enable it to do this effectually, its teeth should not be long, but rather so short that the framework of the implement may rub over the ground.—*M. S.*

On Raftering or Ribbing Land.—Each sod or furrow-slice is, in this operation, turned over upon the own breadth of last land which has not been ploughed. The ridged surface of ground ploughed in this way is greater than that of ground ploughed in ordinary fashion. There are two opinions on the value of this mode of ploughing—opinions, too, which are held to stoutly by their respective owners. The one party holds forth the advantage of the plan especially in ploughing before winter, by which a great surface is exposed to the frost; and the other holds forth the evil of only half ploughing the land. It is evident that in raftering, only every alternate sod is moved, the other being firm land, on the top of which the sods are laid; and this does not so effectually cover the land as to hinder the growth of weeds. Having been accustomed to see land ploughed deeply and effectually before winter, and having no experience of the advantage of raftering land, I cannot give an opinion of its merits. It appears to me, however, that the weather which cannot penetrate fast land as it can that which is loose, cannot have the effect on the half ploughed or raftered field that it can on the field which is perfectly ploughed.—*M. S.*

On Reaping Grain.—The observations and testimonials in the *Gazette*, on the proper period of reaping Wheat at an earlier stage than is now commonly practised, are only confirmatory of an opinion that has long prevailed, and been partially practised, but not generally been adopted on account of the slow rate of progress in agricultural improvements, and the extreme backwardness with which anything new is received. I remember being told by an old practitioner a quarter of a century ago, that Oats should be cut when "paddy-hued," or when the pickles are striped like the back of a paddock, and I have in many cases cut Oats in that state. I have got the straw more juicy, and better in quality, and the farina finer. In the case of Barley being cut in that striped state, I found it always preferred by the maltsters, the skin being thinner, and the sprout quicker and more vigorous. With these two grains the results were quite decisive. In the case of Wheat, I had a field in Leicestershire cut fully ten days before the usual time, the straw being greenish, and the pickle hard, beyond shrinking, not admitting the striped test, as neither the calyx nor corolla adheres. It was threshed in due time, and sold to a miller of much experience, who remarked the very superior quality of the flour in point of fineness and gift, and could give no reason till he asked me if it grew on the field cut so early, and which in public opinion was so much hurt thereby. He saw the cause at once, but the fact convinced none else. He even declared it the finest article he ever saw. It may be very reasonably supposed that fruits and seeds have passed the adolescent state when the quantity of matter is fully gathered which forms the body; and when this has happened, the matter is in its finest form, and a coarseness takes place immediately on verging into confirmed maturity. The processes of nature universally confirm this observation, and in the case of cutting grain, it only remains to judge at what time the matters composing the pickle have acquired a consistency sufficient to prevent shrinking after the crop is cut. It will be found that this period has arrived some time before the straw and ears have attained the common marks of ripeness—a yellow, gold, or white colour; when they are thus fully ripe, the pickles are pushed much more forward in maturity than the appendages of support. My experience enables me to say, that in most cases our grains are 10 to 14 days too late in being cut; and I am glad to be able to add my testimony to the authorities already adduced.—*D.*

Cone Wheat.—Having recently noticed some very fine Cone Wheat growing near this city, I have had the curiosity to ascertain the length and weight of two ears taken indiscriminately, after removal of the crop from the land, and consequently in a dry state.

Length of ear.	Number of seeds.	Weight (Apothecary's).
6 inches	106	150 grs. or 2½ drs.
5¾ inches	110	156 grs.

In both cases the stalk measured about 5 feet 6 inches.—*F. S., Gloucester.* [Very fine ears.]

Vale of Evesham.—The harvest in this rich and beautiful vale commenced in good earnest about the first week in August. Although the weather was at first fair and promising, on the second week the barometer fell very low and the farmers' spirits more so; however, a brisk wind and bright sun cleared away the storms, and many a thousand load of Wheat was secured in excellent condition. Various were the implements used for cutting down the Wheat: in some fields might be seen the celebrated Welsh bagging-hook, in others the Scotch scythe, and lastly, though not the least effective, the old English sickle. Many commenced reaping this season earlier than usual: some, tempted by the fine weather, others from the numbers of reapers applying to be set on; those who delayed, thinking the Corn was not sufficiently ripe, had a considerable quantity shed upon the ground. The Wheat was remarkably free from rubbish, and consequently soon ready for carting to the stack-yard. The autumn-planted Wheat will average from three to four bags per acre more than that planted late in the spring. Had it answered as well this season as the three last years, a vast many might have been tempted to deviate from the general rule of planting in the autumn; and then, had such a failure as the present taken place, the consequences to the country might have been very serious. Notwithstanding this deficiency in the spring-planted Wheat, the crop undoubtedly is a full average one; and the grain was never known to be finer. The Barley will be a very indifferent crop. Beans are also very short in the straw, and although in some fields well-podded, the crop is far short of an average. Peas, both White and Grey, were secured in excellent condition, and there is little doubt of their proving good boilers; their colour is excellent, and the straw will prove valuable for store stock. Swedes and Turnips are a failure: although the young plants came up tolerably well, no sooner did they make their appearance than the little spotted fly commenced devouring them, and in a very short time afterwards the aphis joined in the work of destruction. After both these annoying little insects had done their best to annihilate the plants, a white grub began gnawing the roots, and finished the greater portion of those that had escaped. Some tried lime, others soot, but the most effective plan that I have heard of in destroying the aphis was adopted by a neighbour of mine. He sowed lime over the young plants, and afterwards passed a hurdle drawn with willow branches, both ways over them—the crop is good. Scarcely one farmer in a parish has a good field of Swedish Turnips; many have sown three or four times, and others have given up in despair. Never was the Swede land more expensively dressed with bones, guano, and all kinds of stimulating manures; notwithstanding which, all have failed. The loss of the Swede crop will be most seriously felt by the large stock owners. The young Clovers amongst the Barley and Wheat present a very poor appearance; few grounds will bear stocking before the spring. Farmers will do wisely to plant as many Vetches as they can—spring keep will be highly valuable. Although reports of the Potato crop are favourable, on a closer inspection they will prove to be incorrect. The early sorts have nearly all rooted again since the rain, and very many of the late Potatoes are full of root without any tubers; only those planted just before the rain in the early part of July are good. The fruit in the Apple and Pear orchards is exceedingly fine and free from blight, and promises to make excellent cider and perry. It is a matter of great thankfulness that the Wheat crop is so good this year. It is now evident that the British farmer can grow sufficient for the increasing population; scarcely a bushel of foreign Corn will be required before another harvest.—*H. H., Jun.*

Are Rabbits Game?—In your *Gazette* of 27th ult. you state "that the tenant of lands, or any person by his direction, may destroy rabbits on such lands without taking out a game certificate;" and you quote Schedule L. of 52 Geo. III. c. 93. Now in two recent Nos. of *Bell's Life* (I think the last published, and the No. 14 days before), an answer to a correspondent gives an opinion quite the reverse. On a point of consequence, it is strange that two such authorities should so differ in their opinions. Would you oblige a subscriber with correct information upon this point?—*No. 5.5.7.* [See Notices to Correspondents in last week's Paper.]

Vetches and Italian Rye-grass.—Mr. Huxtable inquires if Vetches and Italian Rye-grass may be sown together? You remark, "We doubt the propriety of so doing;" you invite information from your correspondents. I now furnish the result of my own experiments. In May, 1842, I sowed a field of four acres with Vetches, Oats, Cow-grass, and Italian Rye-grass; the first crop that season consisted principally of Vetches and Oats, which I took care to cut before the Vetches could destroy the other Grasses. The second crop (that season) consisted of all the Grasses, but now the Italian Rye-grass and Cow-grass prevailed over the Vetches and Oats. We now come to 1843; May 22d I commenced mowing my Italian Rye-grass and Cow-grass, the former prevailing greatly over the latter. The whole field was mowed three times that season, and part of the field four times. Some of the Italian Rye-grass grew to the length of 5 feet 7 inches. Subsoil, gravel and large pebble-stones; previous crop Oats; land very foul, requiring four ploughings; was well limed, and after mowing manured with stable dung, pig's dung, ashes from iron-stone, calcined with anthracite coal, and also the ashes of anthracite coal.—*William Courtes, Ynisceedwyn Iron Works, near Swansea.* [Perhaps you will be kind enough to give us the quantities of the different seeds you sowed per acre. How were they sown?]

House Manure.—Could you not suggest some mode by which the drainage of large mansions might be made use of as manure? In most of our country houses, when not situated near a stream, the drains are, I believe, allowed to lose themselves in the ground at a certain distance from the mansion. Might they not be made of infinite service, by being conducted to a cesspool, into which cesspool, from time to time, might be thrown disinfecting agents, sufficiently powerful to destroy the offensive odour arising from the same? In Belgium these excrements are looked to as the richest manure, but I believe little pains are taken, if any, to overcome its fetid smell, on being drawn forth for the purpose of application to the growing crops—the proprietors of the land being willing to submit to the nuisance for the sake of the value of the article producing it. I have long caused the urine collected from the bed-chambers to be emptied on the dunghcap, as well as the water in which soap has been used; but I should like to make more use of the valuable manure created in my house; and as I am about entering a new residence, in which I can make any alterations I like in the drainage, I shall be glad to receive any hints you may be disposed to give, which may throw a light on this subject. It has struck me that, taking into consideration the quantity of water which would run into a cesspool from the water-closets of a modern mansion, a pump placed in the same would afford a rich and valuable supply for flowers or vegetables, or, if a water-cart were used, for irrigating Grass land with a liquid manure.—*A Constant Reader.* [Instead of letting the drains lose themselves in the grounds, let them all deliver into a tank at any convenient spot, causing everything first to pass through a cesspool, in which the solid matters may subside. The contents of this should be mixed with fresh vegetable mould, and

applied as ordinary manures; and the liquid manure should have its ammonia fixed by sulphuric acid or sulphate of iron (see *Gardeners' Chronicle*, No. 33), and may be used in garden or field, as you choose].

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

On the last day of this Society's meeting at Southampton, Dr. Buckland delivered a lecture on Artesian Wells, in the course of which he made the following remarks on the means of improving land which Geology affords:—In his address, last Wednesday, to the Council of the Royal Agricultural Society, he had spoken of the capabilities of permanent agricultural improvement in Hampshire, and other southern counties of England, especially in the districts between the sea-coast and a line drawn from Dorchester through Salisbury and Winchester to London, including Wareham Heath, Poole Heath, the New Forest, and Bagshot Heath. If the improvement of these wastes by the mineral manures that lie beneath their surface were taken up in a scientific manner, and on a large scale, by great proprietors, or by a land improvement company; small portable steam-engines, and portable tram-roads, may be employed to raise from shafts that may be sunk in any part of this district, and transfer to profitable distances, and spread upon the surface the chalk, and clay and marl, that lie at various depths under the area of these sandy wastes. Thus the silt of the Humber has, with very great profit, been lately transferred by tram-roads to be spread on the surface of barren peat. In Norfolk vast tracts of sandy rabbit-warrens have during the last half century been converted to productive Corn-fields, by adding to their surface a top-dressing of marl, clay, chalk, or shelly sand and gravel, locally called *crag*. The cost of such top-dressings of mineral manure need rarely exceed 10*l.* an acre, and the benefit thereof is the conversion of waste into permanently valuable arable land. On Lincoln Heath, where, not 100 years ago, a land lighthouse was erected to guide the benighted traveller across a barren sandy desert, the application of scientific agriculture and capital had converted thousands of acres of unprofitable heath into pleasant and productive Corn fields. The chalk hills also that form the wolds of Lincolnshire, and the wolds of Yorkshire, had been made rich by processes which were now beginning to be introduced in Hampshire. On Thursday last the Prussian minister had called the attention of the assembled agriculturists of England to the example of good farming that is set them by the most illustrious of living warriors, the Duke of Wellington; and near Strathfieldsaye may now be seen rich fields of Barley and Turnips on naturally heavy clay lands, which two or three years ago were reeking with moisture, and incapable of that rotation of green and grain crops which all good farming requires. The Duke of Wellington was year after year improving his clay lands, first by thorough draining, which is the indispensable precursor of all other improvements, and after drainage spreading large quantities of chalk over the surface of the clay. Not less than 1000 waggon loads of chalk had, during the last year, been brought from Basingstoke to the neighbourhood of Strathfieldsaye. Similar improvements of poor sandy soils may be made by laying upon them a good top-dressing of clay and chalk, in addition to ordinary manures; and Geology had ascertained the existence of several kinds of marl and clay at various depths beneath the poor sandy heaths which form so large a portion of South Hants and Dorset and Berks. The place of these clay beds is often indicated by the oozing of water and growth of rushes near the base of the sloping sides of the shallow valleys or combes that traverse these sandy plains, having their base frequently covered with peat. Between Christchurch and Poole many such oozing streamlets point out spots from which, by the aid of a small steam engine and tram-road, clay may be brought up to reclaim the sandy wastes around each of these centres of supply of fertilising mineral manure; and the efficacy of this process had been shown on a small scale near Poole in little inclosures, made by a few industrious peasants. In Hampshire he rejoiced in the occasion of recording a much greater example of improvements of this order now in progress on the property of Sir W. Heathcote, who has already converted to good arable land large inclosed portions of the sandy surface at Anfield and Cranberry Heath, by enriching them with the permanent mineral manures of clay and chalk. Sir W. Heathcote has also adopted on the farm he occupies at Hursley, the practice of stall-feeding oxen, which is essential to produce the great quantities of manure that are required for the fertilisation of all soils that are naturally poor, and without which the improved fertility of the chalk and sandy lands in Lincolnshire could not be sustained. The conversion of barren soils to fertility, is an example of the practical application of geology to the useful purposes of life, and the sciences of agriculture and civil engineering must obviously be imperfect in some of their most fundamental points, without a knowledge of the composition of soils and structure of the earth.—*Hampshire Independent.*

HIGHLAND AND AGRICULTURAL SOCIETY.

At a public breakfast, on the occasion of the late Annual Meeting of this Society in Glasgow, the following interesting conversation took place, on the subject of Failures in the Potato Crop:—Professor Johnston stated that the disease in the Potato was not confined to this country. It was experienced in France, Germany, Holland, Prussia, Russia, and all over the Continent, as well as in North and South America, showing that some elementary principle was required to cure the evil. The universality of the disease only increased the necessity for discovering its cause; and he expected to derive much information on the point from gentlemen connected with England and Ireland, as well as their own country. He took the opportunity to read a communication from Mr. Girdwood, of Bute, of which the following are extracts:—"In 1838, while residing at Bute, I succeeded in raising a good many varieties of the Potato seed, about half a dozen of these promised to be good kinds, and I continued to grow them till I removed to Ayrshire, in 1841, where I carried a sample of them with me; they succeeded well in 1841 and 1842, and I had every reason to expect they were going to turn out valuable field varieties. Last year, however (1843), they were almost a total failure; still the few that did grow were preserved, have been planted this year, and have become healthy and vigorous. Again, on the same field last year (1843), a plot of smooth beds showed symptoms of disease—in fact, there was a good many blanks, and the whole plot was stunted and weakly. I have this year, by way of experiment, planted a portion of the produce of this plot; farther, I intentionally planted them late when the soil was exceedingly dry, and after the sets had lain out for a week, they have come quite regularly, and look healthy. I shall only further remark, that I have known the plan of keeping those intended for seed in the ground all winter, having tried it for several years past with uniform success."—Mr. Burnet, of Gadgagh, in stating the results of his own experience, said he never planted Potatoes without thoroughly draining and subsoil-ploughing the land. He had experienced no failures in the Potatoes till last year, and that in only one variety, the Rough Reds. This year he had experienced a failure in another variety, the Russian Dons; but this description of failure was very different from that of last year. The general crop is extremely healthy; but here and there, sometimes one and sometimes two have failed. On examining the Potato which had been planted, it was found to be quite fresh, with the skin unbroken, but the plant, which had at first grown up well had withered and died. As to other kinds of Potatoes, he had planted them this year both whole and cut, and there were no failures. He had planted about three acres with guano alone, and without any farm-yard manure, and they had come up invariably vigorous and healthy, except in a very few instances, where the land was not pulverised; and he attributed this, not to the Potato, but to the hardness and roughness of the land, the rest of the field being the most healthy crop he had seen. Another experiment he tried was this:—Last year he planted a variety of Potatoes, and particularly those that were likely to fail, between October and the end of September, at a depth of 12 inches (!) some of them with manure on the top, and some without, and the result was, that those varieties which had failed before failed again. About three-fourths of the crop, however, was good. With regard to the failure that took place in the winter-planted Potatoes, it was somewhat different from that which took place in the spring-planted Potatoes. They began to vegetate in spring, but instead of sending up a sprout, it came only a short way, and formed a tuber on the top.* A less proportion of those planted in spring were good; and he had invariably found that Potatoes left in the ground came up fresh and vigorous without any failure at all.—Mr. Alexander, of Southbar, had grown Potatoes very extensively, and could say from his own experience, that he never had a failure but where the Potato was ill-treated by previous management, by being heated, or otherwise. They were pitted in too large quantities, and these bins all heated more or less. He had never seen a failure in Early Potatoes, which was, in his opinion, accounted for by their never being stowed away in such large quantities; and they were, besides, never so ripe. He found great advantage from putting in Potatoes early, while the land was still moist, and then covering them over with dry gypsum.—Mr. Allison, of Mearns, said, he believed vegetable life was just like animal life, in so far as it would be injured by bad treatment. He had seen whole Potatoes grow frequently where cut ones failed, though if the latter did not fail, they produced better crops than when whole. He also found that the Potatoes were stronger for seed when they were reared from whole Potatoes. If they were raised for two years from whole Potatoes, his experience led him to believe that disease would be cured; they should just allow them to remain in the ground, and never touch them.—Mr. Anderson, who has the management of large estates in the northern parts of Ireland, had watched narrowly the progress of Potato-growing for many years. He had found that where the land was well drained and pulverised, failures seldom occurred. His plan on his own farms was, to drain thoroughly, pulverise the soil, open the drills, and put in the sets, and cover all up in half an hour with the plough; and with this treatment he never had a failure; and when he left them exposed to the sun he found that they always failed. He tried the practice of digging the Potatoes before they were top ripe. The farmers around complained of this, and would not take their seed from him, because they were not ripe; but he had derived great advantage from the practice. He employed careful people, too, to select for seed those Potatoes that had not been injured, and he never planted a Potato that had been injured by the grape or otherwise. In stowing away seed Potatoes he used a long pit, two and a half feet wide at the bottom, and well drained, covering it well up to keep out the air, and never opening it till the seed was to be planted. While cutting the Potato for seed, if it dried into a mealy, starchy substance, then it was considered good, and sown; but if it was watery, then it was rejected. He had sometimes got the farmers to wash the seed in pure fresh water, and then had the ground pulverised all over with lime, &c. He might say that, during many years, he never had a failure in Potatoes, except in one instance, when, during his absence in Scotland, they were allowed to become too ripe, and the land-steward put a large body of them together, when they heated and rooted. In Armagh, through a great part of which he had travelled investigating this subject, he found that where the land was thoroughly drained and subsoil-ploughing attended to, there was no failure.—Mr. Stefling, of Kenmure, gave some interesting details regarding the introduction of the Potato into this country. He said Gerard, an old English botanist, raised seedling Potatoes in 1590; they were planted in the open field in England in 1684; and they were planted in a similar way in Scotland by Thomas Prentice, a day labourer, at Kilsyth, in 1728; they were introduced to Ireland about 1610, by Sir Walter Raleigh. In reference to the taint in Potatoes, he might state that there was no failure 30 years ago, although it was often roughly treated; now disease existed in almost every country where the Potato was cultivated, whether in Europe or America. The oldest varieties, viz., the Rough Red and the Common Red, are most subject to disease; the Cups, one of the newest sorts, blossoms, but seldom bears apples in Scotland; it is one of the most healthy kinds, but within the last two years has begun to fail in Ireland. He believed the disease in this plant was caused by our having allowed it to bear seed annually for so long a period of years—not, as some supposed, by having encouraged it to put forth its productive powers below the surface, but by allowing it to shed its seed to waste on the surface of the soil; he believed that the taint did not arise from fungus, or disease by contact, for his friend Mr. Houston had this year manured a patch of Potatoes with a cart load of decayed ones, and they gave promise of a good crop. The strongest presumptive evidence which he could offer in favour of his views was, that the late varieties, which blossomed freely, are those which are tainted with this disease, whilst the early varieties, which rarely blossom, are free from it. Why then does not the farmer pluck the blossom in his Potato fields, when it has been proved that this practice gives an extra weight of produce? It is because he is not convinced that by allowing the seed to ripen he exhausts not only his soil but his Potato plant, and loses starch from the tubers. He at one time thought that by plucking off the blossoms of our present stock of Potatoes, the disease might be arrested or cured; but he learned last week that some varieties raised from seed a year or two ago were already decaying—thus proving that a "corrupt tree could not bring forth good fruit." Under these circumstances he saw no alternative but to get a fresh supply of seed—and the sooner the better—from Peru, or any other native country of the Potato, where fresh plants have been allowed to come up every successive year. Unless something were done, the Potato might degenerate altogether.—Sir Robert Bateson, from Ireland, begged to state a few facts from his own experience. On one occasion he left Potatoes in the drill during the winter, covering them well up, and the next season, when planted, they grew up a very fine crop. These, from the time they were in the ground, must have been dead ripe. The only drawback to this was, that it prevented the farmer from occupying the ground with other crops; but he thought it would be found advantageous to lay aside a field for this purpose. He planted a field in autumn, which came up without a single miss, and most vigorously, but, strange to say, they continued growing to a later period than those planted in the spring. Perhaps this was caused by their being planted deeper than the spring Potatoes, to protect them from the frost. He learned a fact from Mr. Reid, of Derry, which was worthy of attention. This gentleman raised his Potatoes and spread them in the sun, till they became dried and unfit for food; he then stowed them away, and when planted, never knew a failure. He found that whole Potatoes never failed, but they yielded a smaller crop, and much smaller Potatoes than the cut ones. It was his practice, as soon as a few shaws became ripe, to dig the Potatoes, as he entirely disapproved of ripening too much. Mr. Fleming, of Barrochan, could confirm the fact, that if Potatoes were left in the ground the whole winter through, they never failed; and the later Potatoes were in being planted, and the less ripe they were, the less likely were they to fail. He had always found, that the worst eating Potato, the worst in quality, was the best for seed, and the least likely to prove a failure. Several years ago he had tried to raise Potatoes from seed, under the idea that the plant had become degenerate; but after innumerable trials, and raising many thousands of plants, he had never produced one single healthy variety; therefore, they must look to something else than the mere seed to produce healthy Potatoes, and, in his opinion, the only thing likely to do this was the introduction of some other mode of treatment. What he had found as likely to produce a more healthy Potato for planting was dressing the Potato with nitrate of soda, and sulphate of soda and magnesia. This gave a crop which, when planted, grew more surely than others. His Potatoes, dressed in this way, were all growing well this year, and they had more vitality than when raised by the common farm-yard manure.—Mr. Alexander said a person who made a great deal of starch got his Potatoes from a person in his neighbourhood, and it was found that the best Potato for starch was the worst for seed.—Mr. Anderson said,

* The depth at which they were planted was evidently one cause of the failure of the winter-planted Potatoes.

several years ago he tried the experiment of cutting the flowers and apples off every four alternate drills before they came to maturity, and allowed the Potatoes in the other drills to bring forward their seed to maturity. He planted the Potatoes, but never could see the slightest difference between the one and the other; in short, it would not pay the expense.—Mr. Fleming had always observed that Potatoes shallow planted, and where there were a good number exposed to the air, so that they became quite green, made the best seed. A great injury was done to Potatoes by deep planting, as it was absolutely necessary that they should have free access to the atmosphere.—The Chairman said, it would be of great advantage to the meeting if, after the valuable information they had received, Professor Johnston would sum it up before them, and perhaps endeavour to reconcile some contradictory statements which had been made.—Professor Johnston then went over the leading facts brought forward by the previous speakers, and pointed out their value in so far as they suggested to others the propriety of making them the subject of experiment. For example, the plan followed by Mr. Burnet and others of planting Potatoes in autumn, as a surer way of getting a good crop; the course of treatment before planting recommended by Mr. Alexander, viz., to keep them in small bins to prevent heating; the proposal of Mr. Allison to plant whole Potatoes; the suggestions of Mr. Anderson, who recommended well-drained and pulverised land, also opening the drills, putting in the manure and the seed, and covering them up immediately, together with his plan of using green Potatoes for seed; the opinion of Mr. Stirling, that the failures are owing to the seed being grown over a long period of years; and the suggestions of Mr. Fleming and others—all these were matters of great importance, and such as gentlemen should take into consideration, and make the subject of experiment for themselves.—Sir Robert Bateson said he had found a small Potato which grew out of the stem, produced by the juice, which when planted produced excellent crops.—The Chairman then shortly addressed the meeting. They had been engaged in a question of vital importance, and he would appeal to every gentleman present if they had not received much information. He would only express his hope that the meeting that day would be followed by other meetings of a similar character, and he would suggest that sound practical farmers, like Mr. Allison, should be brought forward to such meetings to give the results of such experiments, from which all might derive solid and truly useful information; while men of science, like Professor Johnston, could digest that information, and reconcile what appeared inconsistent; and he had no doubt, notwithstanding the forebodings of Mr. Stirling, that the cultivation of so invaluable an article of food as the Potato would be greatly improved and extended. The meeting then separated.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

The following remarks on the great Annual Meeting of this Society, at Dublin, on Aug. 14th and 15th, are extracted from the *Dublin Farmers' Gazette*:—Amongst the live stock exhibited were very many which, in the opinion of the Judges, would not only have been creditable, but which could hardly be excelled at either of the national Shows of England or Scotland, especially amongst the Bulls; but in all the other classes, together with some splendid animals, the great majority were very inferior; neither in any other of the Cattle Classes did the stock come forward in the usual proportion to the entries; and the vacant stalls thereby occasioned gave a scattered appearance, which bore the semblance of an attempt to spread a few cattle over an immense extent of ground. Much of this deficiency was doubtless caused by the unfortunate prevalence of the distemper; but much more, we fear, by the classification which the Society, departing from the track that has led to such happy results in other Societies, has struck out for itself. The novel distinctions of "Pure and Distinct Breeds of Cattle for Breeding Purposes," and of "Pure and Distinct Breeds for Fattening Purposes," were not understood by our breeders. Up to this time, the effort has been to produce animals possessing both qualities in the highest degree of perfection; and being now, for the first time, called on to produce pure and distinct breeds for each purpose, and left in ignorance as to the meaning of the terms of competition, no wonder they should refuse to send forward their animals, or having sent them, find that they might better have kept them at home. The competition in sheep was by no means so extensive, nor were the lots individually, with some exceptions, equal to our expectations. The Horse Class contained a few fine animals, and may be characterised as respectable; and, as regards swine, we have seen a greater number, and, with few exceptions, superior animals at many of the provincial Shows. We have now arrived at a department of the Exhibition which was really excellent—that of the Agricultural Implements. In mechanical invention, evident efficiency and workmanship, nothing which we have ever before seen could be compared to the implements offered for competition by the Scottish manufacturers, Wilkie, Law, and Grey. As a general collection, that exhibited by the Messrs. Drummond was most creditable, containing, as it did, a full assortment of the most valuable implements; nor were the large contributions of Messrs. Sheridan, Courtney, and Stephens, Lestrange and Bambrick, and Murphy, and Messrs. Paul and Vincent, much inferior, either in execution or apparent efficiency. Mr. Robinson's, of Lisburn, churning and steaming apparatus were most deservedly admired.

The following is the award of Prizes for the Implements exhibited:—

For the best general assortment of collected Implements, to Messrs. Drummond and Co., Dublin, 5*l*.

For the best general assortment of Implements of Irish manufacture, to Messrs. H. and J. Sheridan, Dublin, 4*l*.

For the best Swing Plough exhibited, to Messrs. Drummond, of Stirling, for Barrowman's Plough, the Society's Medal.

For the best Swing Plough manufactured in Ireland, to Messrs. Sheridan, Bridgefoot-street, Dublin, the Society's Medal.

For the best Subsoil Plough exhibited, to Mr. Wilkie, Glasgow, the Medal.

For the best Subsoil Plough manufactured in Ireland, to Messrs. H. and J. Sheridan, Dublin, the Medal.

For the best Turnwrist Plough, to Mr. Wilkie, Glasgow, the Medal.

For the best Turnwrist Plough manufactured in Ireland, to Messrs. H. and J. Sheridan, Dublin, the Medal.

For the best Grubber, to Mr. Wilkie, of Glasgow, for his Finlayson's Grubber, the Medal.

For the best Horse Hoe, to Mr. Wilkie, of Glasgow, the Medal.

For the best Turnip Drill, to Messrs. Drummond and Co., Dublin, the Medal.

For the best Turnip and Bone-dust Dropping Machine, to Messrs. Drummond and Co., the Medal.

For a Machine for sowing Carrots, to Messrs. Drummond and Co., the Medal.

For the best Corn and general Drill Machine, to Patrick Gogarty, of Castlebellingham, 2*l*., and the Medal.

To Joshua Anderson, of Dublin, for a model of an improved method of Slating, 2*l*.

To Mr. Bigg, Crawford-st., London, for his Sheep-dipping Apparatus, the Medal.

To Messrs. Courtney and Stephens, Dublin, for their improved Hay-tedder, the Medal.

To the same, for their Water Barrel, the Medal.

To the same, for a Clod Crusher and Bar Roller, 2*l*.

To Mr. F. W. Etheredge, for his patent Tile-making Machine, 5*l*. and the Medal.

To the Hon. C. J. Trench, for his Model of a Cottage with Offices, the Medal.

To John Gwynne, of Bushmills, county Antrim, for a collection of Draining Tools of native manufacture, 2*l*. and the Medal.

To W. Langford, of Newtownbarry, for his Self-adjusting Tumbling Carts, 2*l*. and the Medal.

To Robert Law, of Shettleston, Glasgow, for his Farm Cart, the Medal.

To the same, for his collection of strong and useful Implements, 3*l*.

To John Martin, Peter-st., Dublin, for Rodway's Horseshoe, the Medal.

To John Molloy, Rutland-square, for his newly-invented Hames, trace fastening to swing bar, the Medal.

To Messrs. Paul and Vincent, Blackhall-place, Dublin, for their Threshing Machines, the Medal.

To same, for their simple Beam and Scales, 2*l*.

To James Richmond, of Salford, for his Improved Chaff Cutter, the Medal.

To the same, for his Beam and Oat Crusher, the Medal.

To the same, for his Improved Churn with right and left-hand motion, the Medal.

To the same, for General Excellence of Workmanship, 3*l*.

To Messrs. H. and J. Sheridan, Dublin, for their Improved Weighing Machine, the Medal.

To Mr. James Willis, Dublin, for Herbert's Patent Flower Mill, 1*l*. and the Medal.

To Mr. James Wilkie, Glasgow, for the superior workmanship of his collection of Implements, 5*l*.

To D. J. Wilson, Esq., Belvoir, for his Model of a Labourer's Cottage, the Medal.

To Richard Robinson, of Lisburn, for his Steaming Apparatus, the Medal.

To the same, for his Water-case Churn, the Medal.

To the same, for his General Scientific Arrangement, 3*l*.

To R. Gray, of Uddingston, for a collection of good and well-executed Implements, 3*l*.

To F. M'Neill and Co., for their Roofing Felt, the Medal.

To T. G. Stoney, Esq., for his Model of an Agricultural School, the Medal.

FARMERS' CLUBS.

Wetherby.—The first quarterly meeting of this Society was held on the 1st inst. The attendance of members was numerous, and after an interesting and highly-instructive discussion upon the subject proposed, viz., The best Method of Harvesting Wheat and Barley, including the Period and Method of Cutting and Securing, the following resolutions were agreed upon:—1st, That the best time to cut Wheat is when the grain is in a raw state, and the Straw beginning to assume a yellow hue up to the ear, or from ten to seven days earlier than is customary in this district. 2d, That the best time for cutting Barley is when the Straw and grain are fully ripe. 3d, That the best method of cutting both Wheat and Barley is by mowing; and where Clover or Grass seeds are growing, it is desirable to leave the stubble not shorter than four inches. 4th, That round stacks are better than long ones.

Miscellaneous.

Improvement of Cold and Heavy Soils by Burnt Clay.—The first field, (5 acres,) is valued at 7*s*. 6*d*. per acre. I entered upon it 1839, a foul Bean-stubble; the following May it was skim-ploughed to the depth of about 1½ inch, and all that the plough raised burned with faggots, at the cost, including spreading, of 42*s*. per acre. It was then ploughed and scuffled, and the weather being favourable, was rendered perfectly clean; then planted in October with Vetches, which, the following summer, were eaten off by sheep folded upon them; succeeded by Wheat (1842), which produced 226 bushels, of 62 lbs.; or 1 bushel more than 45 bushels per acre. It was sold at 7*s*. per bushel; and this crop therefore produced more than the fee-simple of the land in its former state. This field is laid down, and is looking very well. A small field of three acres adjoining was similarly treated at the same time, with nearly equal results; the difference in the Wheat-crop, which was not quite so heavy, being attributable to the Vetches having been eaten off by horses tethered on them instead of by sheep. The second instance of the power of ashes, unaided, in rendering exhausted land capable of producing a crop, is, I think, even more conclusive than the first, as it may be said that the great crop of Wheat produced in the former case was attributable to the manure left by the sheep in consuming the Vetches; and this is correct in a degree, but I know not how that crop of Vetches could have been obtained to create that manure without the ashes. In this case, however, the land received no such assistance. It is a field called the Brake Ground—10 acres of exceedingly stiff clay, valued at 25*s*. per acre; and was (Michaelmas, 1829) an awfully foul piece of two years old—I was going to say, seeds—however, it had been down two years; and, for want of something more fit, I was induced to plough and plant it with Wheat—and a miserable speculation it proved. The seed-time of that year, as most of us in this part of the country very well remember, was exceedingly wet. This, combined with the bad state of the land, left me no resource but to dibble it; this was done as well as it could be, and after being twice hoed the following spring, the crop was as nearly as possible 16 bushels per acre. Here then was a stubble in the best possible state for burning, and the weather being dry after harvest, it was skim-ploughed, and attempted to be dragged, but that was impracticable—it was so tied together that it could only be parted with forks, which increased the expense of burning this piece to 50*s*. per acre; but it was well repaid: the quantity of ashes burnt could not have been less, upon by far the greater part of the field, than from 150 to 200 yards per acre. It was then planted, after being ploughed, with Vetches; but such a crop of Crowfoot, Charlock, and rubbish of all descriptions came up the following spring, that I had all mown off together, and carried to the fold-yard. I then proceeded to fallow it, but, as if this field was to be unfortunate, the latter part of the summer proved wet, and it was very imperfectly done, and after draining, was left till April, 1842. The whole of that month proved dry; the field was forked, at an expense of 25*s*. per acre, and by that means rendered clean at last. No rain fell till the night of the 11th of May, and on the 12th and 13th it was drilled with Barley, the produce of which, fit for and sold to the maltster, was 56 bushels per acre. The next crop was Beans, mixed with a few Grey Peas, and certainly the greatest crop of straw I had ever seen. What the produce may be I cannot yet say, but I shall be enabled to inform you, as it is stacked by itself; but I should suppose nearly or quite as many bushels as there were of Barley. All these pieces of land to which I have now alluded had the ashes burned and spread upon the field, at the expense, as I have said, of from 40*s*. to 50*s*. per acre; the greater part done with wood out from the hedges, the value of which I can scarcely state. When that was all exhausted (a good deal having also been used to put upon the tiles in draining) I had recourse to coals, and can state the expense. Three tons of raked stack, which costs here from 9*s*. to 10*s*. per ton (at the pits 3*s*.) will burn in the summer in heaps of about a cart-load each—more than 100 yards to the acre. I have had in some cases much more than this done; and as the labour of burning with coal is rather less than with wood, the whole can be well done at a cost of 3*l*. 10*s*. per acre. But there is another mode of procuring ashes, which, though somewhat more expensive, has its advantages; these are, that it can be done at a time of year when the other mode would be impracticable from wet; and also, that in doing it, the banks, borders, and high headlands, frequently seen in old inclosures, are removed; it is by burning these in large fires of 50 to 200 yards with coal, and carting and wheeling the ashes upon the land. I have done a good deal in this way; and the cost, not including horse labour—which, of course, varies with the distance to which the ashes have to be drawn—is as follows:—

	£	s.	d.
100 yards per acre, labour to burning, at 6*d*.	2	10	0
2 tons of coal, at 9*s*.	0	18	0
Wheeling and spreading a distance of 50 yards from the heaps, and filling and spreading the remainder, 100 yards, at 1½*d*.	0	12	6
	£4	0	6

I give you the following as an instance of the effect of this latter mode:—A field of clay-land, called Bitton—20 acres, worth 28*s*. per acre—was Wheat in 1842. During the following autumn and winter I had the banks and headlands all round the ground burned, which produced 2400 yards of ashes, 400 of which were drawn to another field. Part of the piece, about 5 acres, was planted with Vetches, which were mown while green for fodder for the sheep, to eat while consuming the Turnips upon the other 15. Upon these 5 acres a dressing of ashes, 100 yards to the acre, were spread when the Vetches were removed; and after being cleaned by the requisite ploughings and scuffling, it is now planted with Wheat. The crop upon this portion of the field must therefore depend entirely upon the ashes: it has derived no benefit from the Vetches. Upon the 15 acres, which were dressed in like manner during the winter, where no attempt was ever before made to grow Turnips in consequence of the tenacious quality of the land, and without the aid of manure of any description, except the ashes, I have had a very excellent crop; and the most extraordinary part of the matter is, that though the greater part has been eaten off in the months of October and November last, which were very wet, by nearly 400 sheep constantly kept upon them, the nature of the soil has been for a time so changed by the ashes, that I have been enabled to plough close behind the sheep, and drilled the Wheat as fast as ploughed. For those who, like myself, have undertaken the task of getting a considerable tract of foul and poor clay-land into a tolerable state of cultivation, there are, to my knowledge, no means by which it can be accomplished in so short a time, and with so great a certainty, as by burning. Let it be accompanied in all cases by draining; let the first crop be a green one consumed upon the land, and the land will be at once established, and may ever after, at the least possible expense, be maintained in a productive state, provided it be kept clean and cropped in a fair and reasonable manner.—*C. Randell, in the English Agric. Soc.'s Journal.*

Bone-dust on Pasture Land.—There is, perhaps, no county in England where the pasture lands (particularly the poorer soils) have been so much improved during the last ten or twelve years as in Cheshire; and this principally by the application of what is termed bone-dust. This extraordinary manure has a peculiar effect upon the poor clay land pastures, for on the application of boiled bones a sudden change takes place in the appearance of the fields, and instead of the carnation-leaved, or pink Grass, which so much abounds on this kind of land, a luxuriant herbage presents itself, consisting of red and white Clover, Trefoil, and other Grasses, of which the cattle are so fond that they eat up almost everything before them; even Thistles and Rushes are very much weakened, and eventually reduced, by being constantly eaten off by the stock after the pastures have been bone-dusted.'—*Mr. Palin on Cheshire-farming, in the English Agricultural Society's Journal.*

Growth of Beans and Cabbages together.—The Beans are dibbled in February in double lines four inches apart, and with an interval of three feet to the next row. This enables the double mould-board or the subsoil-plough to pass freely along without injury to the Beans, as often as the state of the soil may require it, until the time of planting the Cabbages. The latter are of the thousand-headed sort, and should have been raised the previous autumn, then pricked out in March (in a corner of the garden), and finally planted in their places between the rows in the field in May or June, taking advantage of showery weather for the purpose. The distance from plant to plant is about two feet; they should be from five to eight inches out of the ground. They do not grow much until after the Beans have been removed, which is generally done early in August. When the latter are gone, the space they occupied is ploughed, and the Cabbages grow with such rapidity as effectually to prevent any weeds from making head that season. No one, ignorant of the practice, sporting over the field in the beginning of September, would imagine that the then luxuriant crop was the second of the season. The Cabbages yield a great bulk of green food towards Christmas, and if their leaves are then pulled, a second sprouting takes place at the end of March or the beginning of April; but as food is of much more consequence to a breeding flock at the latter period, they have been left (without plucking from them in December) till the Turnips are over. They are then eaten on the ground by couples, and the land is ready with a single ploughing for any sort of spring Corn. The quantity of keep derived from them by this arrangement is equal to what the same extent of Turnips would give, but inferior to Swedes. I was led to try the experiment for the first time in 1838, from having accidentally read an account of the husbandry of M. de Fellenbergh, at Mofwyl, in Switzerland, in which a similar custom is mentioned. The success has been complete, and it has never been omitted for a single year since its introduction at Ookham; and I see that, so far from the Bean crop being diminished (in consequence of the greater distance at which the rows are planted to admit the Cabbages between them), it has, on the contrary, been increased from about 35 bushels, the average yield for five years before the mixture, to 41 bushels, the average yield for five years, since the Cabbages were introduced. —*Earl of Lovelace in the English Agricultural Society's Journal.*

Cottage Allotments.—About three years ago I selected two pieces of land, together about 30 statute acres, from a farm of Lord Crewe's, which land had been very hard tilled, and, lying more than a mile from the homestead, had not for many years received any support in the way of manure—besides which it was naturally a weak light soil, with a bad subsoil; and so little did the tenant prize it, that he said I was quite welcome to take it from the farm if I would release him from the rates and taxes paid in respect of it, and make any deduction from his rent I might think proper: this I did to his satisfaction, and set it out in proper allotments, averaging about half an acre each. I allowed the poor men draining-shells, which they put down themselves under my directions, and charged them as much rent as was just sufficient to cover the rent formerly paid by the farmer, together with all levies, tithe, rent-charge, &c.; and although the land has only undergone this superior method of cultivation for three years, and was in the lowest condition to commence with, and consequently will improve for years to come, yet notwithstanding these disadvantages the crops grown upon these 30 acres of poor land last summer were as follows:—1497 measures of Potatoes, 298 measures of Wheat, 22 measures of Barley, 10 measures of Vetches, and 70 measures of Oats; which crops, after paying the rent, poor-rates, tithe, and all other charges, amount to nearly 250*l.*, even calculating them at the present low prices of agricultural produce. It is, therefore, impossible that this amount of produce could be distributed amongst these poor men without adding greatly to the comfort of themselves and their families; besides which all these necessaries of life were procured by the application of those leisure hours which would, most likely, have been spent in the beer-house, and might have produced the bitter pains of domestic strife and wretchedness, instead of making the cottage a peaceful and happy home, and the allotment a healthy training-school for the children. I am extensively concerned in the management of cottage property, and necessarily come in contact with some hundreds of cottage tenants (and, I hope, I pay some attention to their habits, wants, and feelings), and I am decidedly of opinion that no able-bodied labourer ought to have less than half an acre of land, which will enable him to raise Potatoes sufficient for his own consumption and to fatten a couple of pigs, besides growing a little bread-corn; and I think it would be for the general good of the agricultural community if every cottager with a family was enabled to keep his cow.—*Mr. Palin on Cheshire-farming, in the English Agricultural Society's Journal.*

Utility of Peat-Ashes.—Peat-ashes cannot be said to have been totally overlooked or disregarded throughout England, though they are so very much in Scotland and Wales; and, indeed, they are only very partially used in England, where their manufacture is almost exclusively confined to Berkshire and Hampshire, and some few spots of Bedfordshire, but from whence they are carried by land for upwards of thirty miles, and sold at about 9*d.* per bushel. Indeed, so strong and powerful is the peat-ash that is burned in immense heaps at Woolhampton, near Newbury, that ten bushels per acre are sufficient to apply, but the usual average elsewhere runs about thirty bushels per acre. Considerable doubts have been expressed as to the quantity of peat-ashes to be used per acre on an average; but this cannot be exactly defined, as so very much must always depend upon two several points—first, the preparation of the ashes, and their sorts; and, second, the various soils, and their various natures, on which the ashes are to be used. One general rule as to the method of preparing the ashes may suffice, as the best and most approved one, which is to have the peats cast in their proper season, and properly dried, and to be burnt in a kiln, properly covered in at the top, with a quick draught. This is the method of treating the "best cast peats," but the top, outsides, and the sedgy and even foggy peats, may be burned in conical piles, and may still be brought into useful application, by making a freer use of them, as this mode of burning this class of peats will cost but very little, and the outside cover has only to be pared away to get at the under and best ashes. But taking the average run of peats, neither the best nor the worst, the quantity per acre may fairly be stated, as an average, at from twenty to thirty bushels per acre, and for old upland meadow, or any old green-sward, this quantity will produce as much or more Dutch Honeysuckle and small herbage as either soot or ashes from sea-borne coal, at one-sixth of the cost, and, when mixed with lime or fine sand, will not only be a very superior top-dressing for all upland and other meadow, and Red Clover without Rye-grass, but will also prove a most valuable compost and manure for Carrots, Parsnips, or Mangold Wurzel, when used in stiff ground, with a strong and large dibbling stick, as is used in Leicestershire or Warwickshire, in all heavy grounds,* and for Potatoes in common drills. The value of the peat-ashes in Warwickshire and Leicestershire is from 9*d.* to 1*s.* per bushel, and as climate, or too great a similarity of soil may be brought forward as an objection, the writer begs leave to say he has tried these ashes in the bleakest and least protected part of Aberdeenshire, with greater success than he ever did in Hertfordshire, Warwickshire, or Leicestershire, and he feels confident that these peat-ashes need only be generally tried to be as generally esteemed and used all over Scotland.—*The Earl of Strathmore, in the Transactions of the Highland Society.*

* This method of dibbling Carrots, Parsnips, and Mangold Wurzel, with peat-compost in the heavy lands in Leicestershire and Warwickshire, has uniformly succeeded where every other culture and manure have failed, and is managed thus:—Plough your land in the end of September or beginning of October with a good strong furrow, and in the month of March (about the middle) let your dibblers begin, always dibbling backwards, and making a hole about as wide as a pint bottle, and thirteen inches deep; fill up the hole with the peat-compost to within four inches of the top. Put into each hole eight or ten seeds, cover them over with the peat-compost till level with the ground, then draw a slight but strong "bush harrow" over them. When they have shot, let the three best shoots be left, and the rest weeded out carefully, as they may do to transplant and fill up any vacancies where the seed may have failed. This will be done by women and children better than by men. Let the remaining plants be earthed up, and this will be as good as one hoeing, and, on a second and final looking over the middle-holes, let all the plants be removed but one, and earth that well up. In the very deep lands in Leicestershire, which will not bear a cart in the spring, dunlaps are used with large cushions to carry the compost up and down each furrow, which dispenses very well, and does not poach the ground like horses and the lightest mounted carts.

Notices to Correspondents.

Alpaca.—*Viverium*—It is the name of that variety of Llama which yields wool. The other variety, which is nearly naked, is used in Peru as a beast of burden. See article "Llama," Penny Cyclopædia.

Application of Galvanism.—*Anon.*—Perhaps the following extract from a New York paper may assist you. We do not know, though it came from America, whether or not it be, what it looks like, an Americanism:—"At a late meeting of the Farmers' Club in New York, Mr. Ross presented a Potato 7 inches in circumference, and others no larger than Peas, all planted in the same soil, at the same time—the 25th of May. The large one was from a small plot under the influence of a galvanic battery. Plates of copper and zinc were placed at distances of about 200 feet apart, the Potatoes planted between. They were connected by a copper wire. This formed a battery, the moisture of the earth exciting the galvanic fluid, which was thus constantly passing through the soil in which the Potatoes were planted."

Boast's Patent Manures.—*P.*—We have no experience of them. Purchase guano in a safe quarter, and you *know* you buy a useful fertiliser.

Books.—*T. Wighton.*—Low's "Elements of Practical Agriculture."

Cultivation.—*Humbug.*—Use a scarifier or grubber, and work the land lengthwise and across; harrow, gather weeds together, and burn; then you may plough, and use the scarifier again across the furrows; harrow as before and burn the weeds; that will clean your land. Cart on 30 cubic yards of farm-yard manure per acre, and sow Wheat; or, which would be better, plough the land up in ridges, let it lie all winter, cultivate and manure well in spring, and drill in Turnips, which you may eat on the land with sheep, and sow Wheat in November of next year. Good 1st-years' Clover, and Rye-grass may keep 8 to 14 sheep per acre (according to its quality and the size of the sheep), in improving condition for six months in summer.

Depth of Roots.—*J. R.*—We have traced the radicle of the young Wheat plant to a depth of 1 foot when the leaf was not three weeks old. How deep the root of the perfect plant extends we do not know. Perhaps some of our readers have ascertained this; if so, we should be glad to hear from them.

Grass Land.—*Inquirer.*—A farmer would require to see the Grass land which it is proposed to break up, before he could judge whether or not he would profit by permission to cultivate it. If he should prefer it as arable land, he would, of course, be willing to pay a higher rent for it in that condition; if occupying a stiff and wet soil, he would not break up his pasture, though permitted. We do not know if there be a particular species of Oat adapted for winter-sowing. Wheat will diminish in bulk before summer, after threshing in winter, in the proper-portion in which it may have become drier; how much it may generally diminish from that cause we do not know. Can any one give information as to Daniell's manure having proved useful as a manure for Wheat?

Gypsum.—*H. D.*—We cannot imagine that the small quantity of iron mixed with your gypsum can render it at all injurious to vegetation.

Insects.—*J. M. V.'s* grubs are the caterpillars of a moth called Noctua exclamationis, whose history was given in the Royal Agr. Jour., vol. iv. p. 106, together with figures of the insects. We can recommend no better mode of freeing crops of this pest than hand-picking. Its effects have been lately shown with regard to the wireworm in a calculation published in the last Number of the same Journal. *R.*—*W. L., W.*—Your grubs are the same as the above, and we beg to call your attention to their history in the work just alluded to, where the various modes of extirpation are discussed. We feel much obliged by your remarks regarding the wireworm, and would recommend you to try the effect of gas-water upon them in a cup, and ascertain the length of time they can resist its effects. If it be satisfactory, you can prosecute your experiments in the field. The curious snake-like animal changes to a fly called Thereva. *R.*—*A Cotswold Farmer.*—Your Turnips are infested with plant-lice, or aphides; and the animals transmitted are the larvæ of the lady-birds, whose history you will find in this day's *Chronicle*. They are amongst the best friends you have. *R.*

Parsnip.—*J. B. F.*—We do not know the Giant-Cow-Parsnip. It is, doubtless, propagated by seed. We cannot recommend seedsmen.

Sulphate of Magnesia.—*A. L. M.*—The mode in which alum is manufactured, both on the Continent and in Yorkshire, is to roast clays containing sulphuret of iron and potash. The sulphur is converted by heat and subsequent exposure to the air, into sulphuric acid, which combines with the alumina; this is dissolved out, and as it rarely occurs that the clay contains sufficient potash to form alum, (which is a sulphate of alumina and potash), a solution of potash is added to the ley obtained from the roasted clay; it is then boiled, after which the iron is allowed to deposit; and lime as sulphate of lime, if lime exist in the clay, when it is evaporated and crystallised. If magnesia existed in the clay the sulphate of magnesia would be found in the mother water, for water of crystallised sulphate of magnesia and carbonate of ammonia do *not* mutually decompose each other, therefore it is incapable of fixing the ammonia in liquid manure. But ammonia in its caustic state *will* decompose a solution of sulphate of magnesia, precipitating the magnesia as a bulky hydrate of magnesia. Dr. Turner says "The bicarbonates and the common carbonate of ammonia do not precipitate magnesia."—*A. G.*

Water for Cattle.—*Improver.*—Soft water is decidedly more wholesome for both horses and cows than hard water, the latter owing its hardness chiefly to the presence of sulphate of lime (gypsum), or carbonate of lime (chalk), neither of which is desirable as an addition to the element as it comes from the clouds, but renders it more apt to cause spasm of the bowels (cholic). Rain-water is certainly the purest that can be obtained, and only requires care that it does not contain the impurities from the roof of the building, and that it does not remain unused long enough to putrefy. *W. C. S.*

Wheat.—*Improver.*—If you will send your address we shall be happy to forward some for experiment.

Winter Vetches.—*A Subscriber* may begin to sow immediately for his earliest crop if his land be late. The middle or end of next month will be sufficiently early on oozy soils. We do not know the Emperor Cabbage.

Wood-ashes.—*T. W.*—Fresh ashes contain caustic alkali, which, whatever be the form of the ammonia with which it may come in contact, will take from it, by virtue of its greater affinity, the acid which holds it fixed, and thus let it free. If the ashes be old, they will not thus volatilise the ammonia, because the alkali will, by uniting with the carbonic acid of the air, have lost its causticity. The use of guano will not diminish any necessity which may at present exist for the use of lime. If the act of liming increases the produce your land, it will do so just the same, whether the fertility of your land be as it is now, or as it would be were you to use guano. Guano must not be used on land which has been lately limed, for caustic lime would volatilise the ammonia just as caustic ashes do.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Aug. 26.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	10	to	4s	0		
Best Short Horns	3	8		3	10		
Second quality Beasts	3	2		3	6		
Calves	3	8		4	4		
Pigs	3	4		4	4		

Best Downs & Half-breds	3s	10	to	4s	0		
Best Long-wools	3	6		3	10		
Ewes and second quality	3	4		3	8		
Lambs	3	8		4	4		

Beasts, 3063; Sheep and Lambs, 26,500; Calves, 140; Pigs, 220.

The supply of Beasts to-day is larger, but a considerable quantity of very inferior quality; the increase in numbers has, however, had an effect upon the trade, and we cannot this week quote 4s 2d for the best Scots, &c., although some few make it; the Short-horns of good quality find almost as ready a sale as anything, they being now in season, and several have made very nearly 4s per 8 lbs; trade is very heavy among the middling qualities, and some remain unsold. Sheep are again very abundant, and the trade is excessively heavy, we have a very great many Ewes and middling Sheep, but are not over-supplied with the best qualities, consequently the prices with some difficulty are maintained for good Sheep, but several Ewes, &c., cannot be sold at all. Lamb is almost out of the market. Veal is a dull trade—3d is hardly realised for anything. Pork is tolerably brisk.

Friday, Aug. 30.

The supply of good Beef is still but moderate; the trade for that description continues about the same as on Monday; on the whole, the supply is large, and trade heavy; many middling Beasts cannot be disposed of; what are sold make nearly the same as on Monday. The number of Sheep and Lambs is about the same as of late, and prices are about as on Monday; trade seems somewhat more brisk for the best qualities. Veal trade is a little more lively, but the prices are no better. Pork remains steady.

Beasts, 2264; Sheep and Lambs, 26230; Calves, 264; Pigs, 220.

61, West Smithfield.

HAY.—Per Load of 36 Trusses.

Combdown Hoggets	1 0		1 1	Super Fleece, Wool Market.		

COVENT GARDEN, *August 31.*—The continuance of the late fine weather has caused an abundant supply of Fruit and Vegetables to be brought into the market. Wall fruit, in particular, is very plentiful. Trade is, however, unusually dull for the season of the year. Pine-apples of good quality are sufficient for the demand; and hothouse Grapes are also well supplied. Peaches continue to bring nearly the same prices as last week. Nectarines are a little cheaper. Apricots are scarce. Of Plums there is abundance; some good samples of Coe's Golden Drop have been offered during the week; Orleans and Green Gages are somewhat reduced in price since our last report. Among Apples a few good specimens of Ribston Pippin have made their appearance; and a considerable quantity of Williams's Bon Chretien Pear are in the market. Filberts although not abundant are rather on the increase; they bring from 65s. to 80s. per 100lbs. Melons are good and sufficient for the demand. Morello Cherries have not altered in price since our last report. Tomatoes are a little cheaper. Cucumbers are nearly the same as last week. Among Vegetables, French Beans are good and plentiful, Cauliflowers are sufficient for the demand, and Cabbages, Turnips, and Carrots are abundant. Windsor Beans are scarce; Peas are also becoming scarcer, and have advanced a little in price. Little alteration has taken place in the price of Celery, which is rather improving in quality. Onions are plentiful, and Shallots are becoming more abundant. Endive is also supplied in considerable quantities. Cut Flowers chiefly consist of Euphorbia splendens, Ceanothus azureus, Bignonia venusta, yellow and perpetual Roses, Chinese Asters, Lobelias, Heliotropes, Camellias, Sweet Peas, Verbenas, Fuchsias, *Pelargoniums*, Phloxes, and Carnations.

FRUITS.

Pine *Apple*, per lb., 2s to 3s	Cherries, Wall, per lb., 1s 6d to 2s 6d

Spinach, per sieve, 1s 6d to 2s 6d	Chervil, per punnet, 2d to 3d

HOPS, Friday, Aug. 30.

The Market continues very firm. A slight improvement is said to have taken place in the best grounds, which has caused a few purchase to back the duty as high as 130,000*l*; the blighted districts, however, make but little, if any progress, and we still think the duty over rated, unless we get warmer nights. One packet of the new crop arrived on Wednesday, from Herling, Kent, and was sold at 2*l* 12s per cwt: they were very thin and unripe: if this is a fair specimen of the new crop, it will prove very inferior to last year's growth. Picking ought not in our opinion to commence for a fortnight at least, the Hops being so backward.

Patteson & Smith, Hop-Factors.

MARK-LANE, Monday, Aug. 26.

The supply of Wheat by land carriage samples this morning was moderate, and consisted almost entirely of New—the condition and quality much worse than last week, a great proportion having been damaged by the weather; fine dry qualities commanded the prices of this day se'nnight, but the damp and inferior must be written 1s. to 2s. cheaper, and some quantity remained unsold at the close. There appeared some inclination to purchase old Foreign Wheat, where it could be done at reduced terms, but as Factors generally evinced great firmness, the business transacted was not extensive.—In Barley and Peas there is no alteration.—Beans are in good request, and bring very full prices.—Oats sell slowly, and barely maintain our quotations.—The supply of new Mustard-seed consisted of about 600 qrs. in nearly equal proportions of White and Brown.

Friday, Aug. 30.

We have had little English Wheat up since Monday, but the reluctance of Millers to purchase renders it impossible to obtain the rates of that day. In Foreign a few sales were made on Wednesday, at rather reduced prices, which, from the small amount of business doing, must be considered nominal. There is a slight inquiry for Wheat in Bond for export to France and Holland.—Barley and Beans continue inquired after, but cannot be noted higher.—Peas are neglected.—Oats meet an improved demand, and needy buyers are obliged to pay a slight advance.

NATIONAL TESTIMONIAL to Mr. ROWLAND HILL, Author of the Penny Postage, under the Management of the City of London Mercantile Committee on Postage.

Sir George Larpent, Bart., Chairman and Treasurer.

The Committee engaged in this undertaking beg to intimate to the several provincial Committees and others, who are co-operating with them, that it is their wish to close the Subscriptions in the month of September.

To those who have not yet contributed, the Committee again appeal for their Subscriptions, in the confident expectation that few would wish the opportunity of rewarding the author of a plan which has conferred such great social, moral, and commercial benefits on the country to pass by without their having taken part in it.

When the Collection is completed, the mode in which the amount raised is to be presented to Mr. Hill will be determined and made known to the public.

Subscriptions may be paid through any of the London Banks, or remitted by post-office orders, stamps, or otherwise, to the Secretary, Mr. George Wansey, Solicitor, No. 3, Lothbury, London.

INTERESTING TO LADIES. — To MESSRS. ROWLAND & SON, 20, Hatton Garden, London.— "Percy Place, Landport, Portsmouth, April 4, 1844. Gentlemen,—I think it but an act of justice to inform you of the benefit I have derived from the use of your admirable Macassar Oil. About six months ago I found my hair getting daily more weak and thin, and much discoloured from a practice I had adopted of wetting it continually; fearing that I should lose it entirely, and hearing of the efficacy of your Macassar Oil, I have for some time past constantly used it, and the result is, that my hair is now perfectly restored and much improved in appearance and colour, having become thick, dark and glossy; it also curls freely without the use of paper, which it never did before. To all my friends I have warmly recommended your Macassar Oil as an excellent restorative and preservative for the Hair. As I have an objection to see my name in print, I beg you will not publish it; but you are at liberty to show this letter, or make any other use you please of it, and refer applicants to me if necessary, in proof of the efficacy of your Macassar Oil. Your Obt. Servant *"

ROWLAND'S MACASSAR OIL preserves and reproduces the Hair; prevents it from falling off or turning Gray; changes Gray Hair to its original colour; frees it from Scurf and Dandriff, and makes it beautifully soft and curly.

**** Ask for "ROWLAND'S MACASSAR OIL." All others are Fraudulent Counterfeits.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with Lea & Perrins's Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent Sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) James Hosken."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. Lea and Perrins, Worcester; Messrs. Barclay and Son, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet street.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, city, London.—Mr. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Gulley Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., 50s., and 100s. each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, Lambeth Pottery, High-street, Lambeth, London.

D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed.

DRESS AND FROCK COATS.—Superfine Cloth Dress Coats, 30s. to 35s.; Extra Quality, 40s. to 50s.; Frock Coats, with Silk facing, 35s. to 42s.; with Silk Velvet Collar and Silk facing, 50s.; Waterproof Cassterfield, Codrington, and Travelling Coats, 12s., 15s., and 21s.; Waistcoats, &c. 6s. to 8s. 6d; rich Satin, Silk and Cassimere, 8s. 6d. to 12s. 6d.; Trowsers, 6s. 6d. to 10s. 6d.; Doeskin and Kerseymere, 12s. 6d. to 21s.; Shooting Jackets, 10s. 6d., Boys' and Youths' Cloth, Russar Suits, 21s. to 30s. A Suit of Superfine Black Cloth, 2l.; Extra Quality, 3l. 10s. to 4l. At Fisher & Co.'s, Tailors, 31, King William-street, City, ten doors from London-bridge.

FELIX SUMMERLY'S Home Treasury of Books, Pictures, Toys, &c., purposed to Cultivate the Affections, Fancy, Imagination, and Taste of Children.

In one small volume, price 15s.,

PAXTON'S POCKET BOTANICAL DICTIONARY.

In what may be called an age of Cyclopædias, when the compression of a great variety of information into one volume, in order to bring it within the means of persons of all ranks, is so universally sought, it is evidently desirable that the Gardener, and those connected with his profession, should be as well accommodated as other classes in this particular. No such work existing, however, prior to the issue of the present publication, its value will be at once apparent; since it combines the more essential features of a Botanical Catalogue, a Horticultural Guide, and a Technical Glossary.

Besides being of this comprehensive description, it is especially adapted for the Amateur and Floriculturist; who may, by carrying it in his pocket, examine all the plants that are at any time submitted to his inspection, and immediately derive every intelligence respecting the peculiarities or affinities of particular species which could reasonably be wished for. This is an advantage that can only be sufficiently estimated by those who have felt the want of such an assistant; and to all such individuals, as well as to every agent or friend of Horticulture, the Pocket Botanical Dictionary is decidedly indispensable.

Price 7s., illustrated with Wood-cuts of Birds, Cages, &c.

NATURAL HISTORY OF CAGE BIRDS; their Management, Habits, Food, Diseases, Treatment, Breeding, and the Methods of Catching them. By J. M. Bechstein, M.D.

"It will be welcome to every gentleman's library or drawing-room table. It is superbly got up, with an immense number of vignettes, and, in that rivals the beauty of the Annuals."—*Weekly Dispatch*.

"A very delightful book of its kind. . . . . It seems to us an indispensable book for the bird-fancier."—*Spectator*.

London: W. S. Orr and Co.; and W. R. Chambers, Edinburgh.

CANDLES SUPERIOR IN THEIR BURNING QUALITIES TO THE FINEST WAX are now retailed throughout the Country at One Shilling per pound.

Parties who are in the habit of burning two Tallow moulds of four to the pound, are respectfully requested to make the experiment, whether a single "PRICE'S PATENT CANDLE" of six to the pound will not give more light; and whether therefore these candles do not afford a cheaper source of light than the commonest Tallow ones, notwithstanding the difference in price per pound.

Care must be taken to ask for them in the shops under the name given above, as there are some imitations sold under the name "Composite," by which Price's Patent Candles were originally made public.

The Trade may obtain them wholesale from EDWARD PRICE and Co., Belmont, Vauxhall; or from PALMER and Co., Suttle-street, Clerkenwell.

DRAWING-ROOM CLOCKS.—A. B. SAVORY and SONS, No. 9, Cornhill, London, opposite the Bank of England, invite attention to a splendid variety of Rosewood, China, Bronze, and Ormolu CLOCKS; they go for eight days and strike the hours and half-hours. Price 4 guineas, 7 guineas, and 10 guineas each, and upwards. The performance is warranted.

A Pamphlet, with detailed lists of Prices, and illustrated with sketches, may be had on application gratis, or sent to all parts of Great Britain and Ireland, postage free, in answer to a post letter.

BAILY'S SERIES OF WINNERS.—Under the above title, Messrs. A. H. BAILY & Co. have commenced a Series of Portraits of the Derby, Oaks, and Leger Winners, and of other Horses celebrated for their performances. For this purpose they have engaged the talents of Mr. J. F. HERRING, Sen., so well known as the celebrated Horse-painter. The likeness and execution of each is acknowledged to be perfection.

The size of the Portraits is much larger, and as Works of Art they are much superior to anything hitherto published.

No. 1.—BEE'S-WING. 1*l.* 1*s.*

"It is amongst the best, if it be not the very best, of the portraits of race-horses ever painted. It is a perfect representation of the celebrated and wonderful mare, Bee's-wing, perhaps the best that ever ran at Ascot, or indeed, over any other course. Mr. Herring has given a characteristic portrait, full of identity and life; the picture, moreover, is full of pictorial merit as a work of art; the lights are admirably managed, the very horse-cloths, the litter, and the things which are to be seen in racing stables, are all introduced, and made subservient to general effect. The print will be an excellent addition to portfolios and the walls of the rooms of sporting men, and men of taste."—*Times.*

"She is taken in her loose box, with her lively eye turned as it were on the visiter, who may be presumed to have popped in to take a peep at the pride of Northumbria. All the known points of this model of a mare are accurately presented, and her splendid rich bay delineated to perfection; her quarters are accurately portrayed, and she is placed (that great difficulty) naturally, and therefore gracefully, on her legs."—*Era.*

No. 2.—CHARLES XII. 1*l.* 1*s.*
No. 3.—COTHERSTONE, Winner of the Derby, 1843. 1*l.* 1*s.*
No. 4.—POISON, Winner of the Oaks, 1843. 1*l.* 1*s.*
No. 5.—NUTWITH, Winner of the St. Leger, 1843. 1*l.* 1*s.*
No. 6.—CONFIDENCE, the celebrated American Trotter, performing a match in harness. 1*l.* 1*s.*
No. 7.—ALICE HAWTHORN. 1*l.* 1*s.*
No. 8.—ORLANDO, Winner of the Derby, 1844. 1*l.* 1*s.*
No. 9.—PRINCESS, Winner of the Oaks, 1844. 1*l.* 1*s.*

A. H. BAILY and Co., Cornhill.

On the first of November will be published,

JOHNSON AND SHAW'S FARMERS' ALMANAC for 1845. Suggestions for its improvement and corrections are earnestly requested. All Advertisements for its advertising sheets must be sent by the first of October, to the Publisher, J. RIDGWAY, 169, Piccadilly.

Just published, the Thirteenth Edition, price 2*s.* 6*d.*; free by post, 3*s.* 6*d.*,

London: JOHN W. PARKER, Publisher, West Strand.

PRINTED FOR

TAYLOR AND WALTON,

BOOKSELLERS AND PUBLISHERS TO UNIVERSITY COLLEGE

UPPER GOWER-STREET.

DARLEY'S

SCIENTIFIC LIBRARY

FOR THE USE OF

SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

IT is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the public at large. To youth of either sex at public and private schools; to persons whose education has been neglected, or whose attention has not been directed in early life to such studies; and to Artists and Mechanics these little works will be particularly suited. The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible; the demonstrations of propositions are made plain for the mind and brief for the memory; and the Elements of each Science are reduced not only to their simplest but to their shortest form.

I.

A NEW EDITION (being the fifth) *is now ready*,

A SYSTEM

OF

POPULAR GEOMETRY;

Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles.

BY GEORGE DARLEY, A.B.

Price 4*s.* 6*d.*, cloth.

II.

NEW EDITION (just published),

COMPANION

TO THE

POPULAR GEOMETRY;

In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts.

BY GEORGE DARLEY, A.B.

Price 4*s.* 6*d.*, cloth.

III.

THIRD EDITION,

A SYSTEM

OF

POPULAR ALGEBRA;

WITH

A Section on PROPORTIONS and PROGRESSIONS.

BY GEORGE DARLEY, A.B.

Price 4*s.* 6*d.*

"For students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge, article "Mechanics."*

IV.

SECOND EDITION,

A SYSTEM

OF

POPULAR TRIGONOMETRY,

Both Plane and Spherical.

With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.

BY GEORGE DARLEY, A.B.

Price 5*s.* 6*d.*, cloth.

V.

FAMILIAR ASTRONOMY.

BY GEORGE DARLEY, A.B.

WITH ENGRAVINGS.—12mo, 5*s.*, cloth lettered.

"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, not less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr. Darley."—*Sun.*

MIDHURST HORTICULTURAL SOCIETY.—The Seventh Annual Meeting of this Society will be held at the Grammar School, on Tuesday, the 17th instant, when Prizes will be given for Flowers, Fruits, and Vegetables,—the particulars of which may be had on application to Mr JOHN THORP, Jun, Secretary

UNIVERSITY COLLEGE, London.—Junior School.—Under the Government of the Council of the College.—Head Master, THOMAS HEWITT KEY, A M

The SCHOOL will OPEN on TUESDAY, the 24th of SEPTEMBER

The Session is divided in three terms, viz, from 24th September to Christmas, from Christmas to Easter, and from Easter to the 4th of August

The yearly payment for each pupil is 13l, of which 8l are paid in advance in each term The hours of attendance are from a quarter-past nine to three quarters past three The afternoons of Wednesday and Saturday are devoted exclusively to drawing.

The subjects taught are reading, writing, the English, Latin, Greek, French, and German languages, Ancient and Modern History, Geography, both physical and political, Arithmetic and Book keeping, the Elements of Mathematics and of Natural Philosophy, and Drawing

Any pupil may omit Greek, or Greek and Latin, and devote his whole attention to the other branches of education

There is a general examination of the pupils at the end of the session, and the prizes are then given.

The discipline of the school is maintained without corporal punishment.

A monthly report of the conduct of each pupil is sent to his parent or guardian.

Several of the masters receive boarders

Further particulars may be obtained at the office of the College, CHAS. F ATKINSON, Sec to the Council

The College Lectures in the Classes of the Faculty of Medicine commence on the 1st Oct., those of the Faculty of Arts on 15th Oct —Aug. 27, 1844.

RAY SOCIETY, instituted 2d February, 1844.—This Society has been formed upon the principle of the Parker, Camden, Sydenham, and other Societies, for the purpose of securing to those attached to the study of Natural History, such Works on the various branches of Zoology and Botany as could not be obtained by other means; and will consist of original works; of new editions of works of established merit; of rare tracts and MSS; and of translations and reprints of foreign works. Every subscriber of one guinea annually will be considered a member of the Society, and will be entitled to a copy of every work published by the Society. The Council have great pleasure in stating that the number of Members already exceeds 300, and beg to call the attention of their friends to the necessity of sending in their names as early as possible, in order that they may be enabled to determine the number of copies of their works which they ought to print The Council hope to publish two volumes before Christmas, the first of which will consist of translations from the German and Italian, of Reports on the progress of Zoology and Botany during the last two years

Communications on the business of the Society are requested to be addressed to the Secretaries, Dr George Johnston, Berwick-upon-Tweed, and Dr. Lankester, Golden-square, London. Subscriptions to be sent, by post-office order or check, to the Treasurer, J. S Bowerbank, Esq., 11, Park-street, Islington.

GEORGE JOHNSTON, M D
EDWARD LANKESTER, M.D. } Secretaries.

NEW SUPERB SEEDLING CALCEOLARIAS.—The Subscribers respectfully intimate that they have got possession of the entire selected Stock of the above, raised by ISAAC ANDERSON, Esq, Rhyddlan, whether which the Silver Medal of the Royal Caledonian Horticultural Society was awarded to him at their Meeting of 17th May last, and which, at the subsequent Exhibition on the 20th of July last, excited such general admiration; and they will shortly have published a DESCRIPTIVE CATALOGUE of them, which will be forwarded, post free, upon application; but as the stock of Plants is limited, early orders are requested. CARMICHAEL, KELLY, and Co., Florists, Warriston Lodge, (opposite the Royal Botanic Gardens), Edinburgh. N.B.—An Experienced GARDENER, of good character, recommended.

THOMAS JACKSON, Kingston Nursery, Surrey, Sept. 6.

MR HOYLE'S NEW SEEDLING GERANIUMS.

WILLIAM MILLER respectfully announces to the Nobility, Gentry, Amateurs, and the Trade, that he has purchased the entire stock of the following superb SEEDLING GERANIUMS raised by Mr. W. Hoyle, Esq, of Guernsey, viz.

			each—£	s.	d.
1844—	Titus		0	5	0
	Pompey		0	2	6
	Champion		0	2	6
	These three for six guineas.				
1843—	Unique		1	1	0
	Queen of England		1	1	0
	Claude		1	1	0
	Sarah Jane		1	1	0
	Amelia		0	10	6
	Majestica		0	10	6
	Rosalia		0	10	6
	Flora		0	10	6
	General Pollock		0	10	6
	These nine for five guineas.				

The entire set 10 guineas with a discount of 20 per cent, to the Trade A remittance must accompany the order from unknown correspondents

Titus received a seedling prize at Chiswick, June, 1844; Pompey, Champion and Unique were pronounced by Professor Lindley, in the *Gardeners' Chronicle* of June 29, 1844, to be "three flowers of good substance, size, and variety;" and Mr. Glenny, in *Gardeners' Gazette* June 22, 1844, says, speaking of the Geraniums at the Chiswick Fête—"Mr. Hoyle had by far the best lot there Pompey was the best of them, and Titus next" Blooms of the others were likewise exhibited at the June Fête, Chiswick, 1844 and attracted very extraordinary attention, and were universally admired. On the whole, the above varieties for substance, roundness of form, and general excellent qualities, are among the best ever offered to florists. Printed Lists, with full descriptions, can be had on application To commence sending out plants in October.

W M has been supplied by Mr Hoyle with some choice GERANIUM SEED, which he saved from his own beautiful Seedlings, and the newest and best varieties sent out by other growers Sealed packets of 100 seeds, 12s.; do of 50 seeds, 7s. Also, Hybridised Seed saved from his own extensive collection of Pelargoniums; packets of 100 seeds, 10s.; of 50 seeds, 6s.

Providence Nursery, Ramsgate.

TRUE HIGHLAND PINE

JAMES GRIGOR, NURSERYMAN, Norwich, begs to call the attention of the Land Proprietors of England to this very desirable variety of Pinus sylvestris, which has been raised from seeds collected on the mountains of Strathspey, and of which he has strong plants ready to be sent out. For introducing this tree Messrs Grigor, of Forres and Elgin, were awarded several premiums by the Highland and Agricultural Society of Scotland; and in that part of the country this Pine is rapidly superseding the common soft-wooded variety For all economical purposes it is chief merit consists in the hardiness and durability of its wood hence it is much sought after as pressit for railway sleepers Pictorially considered, or as a landscape ornament it rivals even the Cedar of Lebanon. Mr Walter Scott describes it as assuming much of "the bold and contorted figure of the Oak" and in the last No. of the *Gardeners' Review* it is recommended as a fit tree to be planted in churchyards and cemeteries

Strong plants in pots, such as rabbits and hares will not destroy			5l. each.
Ditto not in pots, 18 inches high			30s. per 100.
Ditto	15	"	20s. "
Ditto	1 foot high		15s. "
Ditto	2 years old		10s. "

J G would recommend all who require them to furnish themselves immediately with these Plants, and to plant them for fall with Spring planting in exceedingly luxurious; and which followed by such a season as was experienced during the commencement of the present Summer, the young trees are sure to be killed

Cedrus Deodara, valued in the open ground, being the strongest plants yet offered, in Bundles, 10s each Araucaria imbricata, Pinus excelsa, Lambii, Benthamiana, &c. &c on reasonable terms.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the gratification of those splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs WARNER & WARNER, Cheapside, London, after the 7th September

TO CALCEOLARIA GROWERS.

THE present being a good time to sow CALCEOLARIA SEED, the Advertiser begs to offer a few packets of his splendid Seed Specified Kinds, saved with great care with printed directions to raise the young plants, at 5s per packet —J. DARNELL, Nottingham, England

EARLIEST STRAWBERRY in CULTIVATION —Rooting Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 30s per 100. As an Early Strawberry it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the "British Queen" Deptford Pine," "Prince Albert," and all the leading kinds. To be had of Messrs. WARNER & WARNER, Seedsmen, 28 Cornhill London

GEO. LIGHTBODY, Falkirk, respectfully informs the cultivators of the RANUNCULUS, that his CATALOGUE of SELECTIONS is now ready, and may be had on application A few Varieties of Superior New Seedlings will be set out this season Gentlemen wishing Auriculas and Ranunculus Seed are requested to make early application, as but a small quantity has been saved this season Packets 2s 6d each

DOUBLE ROMAN and PAPER-WHITE NARCISSUS 4s per dozen The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance and the latter for its purity and elegance have been just received at A. COMPERT'S, late Mr. BARRON'S, Italian and Foreign Warehouse, 18, Pall Mall Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c &c Price Catalogues of which may be had per Post

THE BEST CALCEOLARIAS OF THE SEASON, exhibited by Mr KINGHORN, at the Chiswick Show, in May, and at the Botanical Society in June N GAINES Surrey Lane, Battersea having purchased the Stock of the following beautiful Calceolarias, intends letting them out in a few weeks and as there will be but few plants, early orders are requested

LADY ANN CHARTRIS — Nearly a rose flower, richly mottled with bright yellow and rich light and dark reddish brown, nearly equal of each, full average size, shrubby habit very handsome and effective as well as novel "

DUCHESS OF SUTHERLAND —"The largest and best of its class, nearly as deep as it is across richly blotched and speckled with dark-brown upon a gold coloured ground, not equalled in form; shrubby habit"

PROFESSOR WILSON —"Spotted like the leopard upon brilliant yellow ground, brighter and better than Lady Constable, and more inflated a very distinct variety, and worthy of the very best collections"

KINGHORNII —"A very distinct variety full of shaded clouded spots, or very short stripes, upon a dark yellow ground shrubby and rich in habit"

COUNTESS OF MORNINGTON —Darker than the Duchess of Sutherland; good form and very distinct, shrubby habit, and handsome

FLASH —Brighter than any other grown of good habit, very shrubby handsome plant

The first four of these varieties were described by Mr GLENNY in the *Gazette*, and were selected by him from the entire collection as the best, not less for their colours than their excellent form They were also noticed in the *Chronicle*, as the best exhibited at the May Chiswick Show. The last two were not in flower at the time, but have been selected for their approximation to them in most of the particulars

JOSEPH FRYER begs to offer to the notice of the public good Plants of the following —Thunbergia alata superba, and Aurantiaca superba, 4s each; Verbena, 1s 6d; Calantica nigricans 6s; Do Russelliana, 2s 6d; Veronica speciosa, 2s 6d Finest varieties of Fuchsias sent out this year, 2s 6d each; last year's varieties 9d to 1s Finest varieties of Pansies, 6s to 1s per dozen; New Seedling do, Standard 2s each Pansy seed just saved from J F's extensive collection 1s to 2s 6d per packet

The above will be sent by post free as far as practicable, and a remittance is respectfully solicited from unknown correspondents —Clarendon Nursery, Camberwell Sept 6, 1844

CAMELLIA "EMPEROR"

T. DAVIES AND Co beg to inform their friends and the Public that they now intend sending out the above magnificent Seedling, raised and flowered by them in 1843, when it was exhibited at the rooms of the Horticultural Society of London, where it was awarded a Prize, and afterwards spoken of by Dr Lindley in his Report of that Meeting in the following terms, in the *Chronicle* of 25th March, 1844 — "Messrs DAVIES & Co, exhibited a very handsome Seedling Camellia, raised from the seed of C. colvillii, fertilized with the pollen of C. reticula. In the foliage it resembles the older sorts, but the flower, which is large and well filled up, partakes of the form and colour of its male parent A certificate was awarded for it" Price from 21s to 42s Stock positively limited

CEREUS GRANDIFLORUS RUBRA This splendid new variety of Cereus was raised by J. D. Acto in the manner described by Dr. Lindley in the leading Article of last week's Chronicle. Blossoms measure 10 inches in diameter are of a pale red colour, with a shade of purple in the centre The expand about 7 o'clock in the evening and last nearly the whole of the next day, being an advantage over the night blooming, which generally close early the next morning Strong plants are now ready for sending out at 10s 6d each Remittances or remittances required from unknown correspondents —Knowsley Nursery, near Liverpool 7th Sept 1844

DUTCH HYACINTHS

WARNER AND WARNER, SEEDSMEN, No 28, Cornhill, London, respectfully inform the Nobility and Gentry their Dutch Flower-roots have arrived in superior condition, consisting of the choicest and newest varieties The Bulbs are unusually handsome and large at moderate prices Catalogues forwarded by post on application.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and dispatch — This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by man or woman It is easily set so as to deliver the exact quantity of Seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Rape Seed, Wheat, Barley, Peas, and all kinds of Garden Seeds. In kind, if 10s each; or with Copper Rack and Pin, 12s each Commission allowed to Agents.

The Dibbles may be obtained of Messrs. CUTHAN and Son, Whisley at Oxford at London, through Messrs Ransome's Agricultural Implement Makers to the Royal Agricultural Society; or from the Inventor, by letter, to his address, Dunhall, near Droitwich, Worcestershire Post-office order for the amount —RICHARD SMITH,

EXHIBITIONS AT THE GARDEN OF THE Horticultural Society of London,

FOR THE YEAR 1845.

NOTICE IS HEREBY GIVEN that the following are the RULES to be observed at these Meetings —

EXHIBITORS —All Persons, whether Fellows of the Society or not, will be at liberty to send Subjects for exhibition

FLOWER STANDS —Exhibitors of Cut Flowers must SUPPLY THEIR OWN BOXES OR STANDS No box or stand should exceed eight inches in height at the back, or 12 inches in depth from front to back The ends of all boxes must either be loose or made to unhinge

MEDALS AND REWARDS —The Society distributes the following Medals and Rewards,—namely,

	value	£.	s.	d.
C The Certificate		0	10	0
SB Silver Banksian Medal		1	0	0
SK Silver Knightian Do		1	5	0
LS Large Silver Do.		1	15	0
bG Large Silver Gilt Do		4	0	0
GB Gold Banksian Do		7	0	0
GK Gold Knightian Do.		10	0	0
LG. Large Gold Do		20	0	0

Exhibitors to whom any of these shall be awarded can exchange them one for another, or may receive their value in money, or in plate *If within one month after the third Exhibition of the year* no intimation shall have been received from an Exhibitor of the manner in which he desires his Medals to be disposed of, all the Medals due to him may be prepared and *transmitted to him through the usual public conveyances without further notice* In case an Exhibitor shall receive a First Prize in any one letter, he shall not be entitled to receive any other Medal in the same letter, except in *K A, M M*, and *N N*

IT IS, HOWEVER, TO BE PARTICULARLY OBSERVED that if any Exhibitor shall obtain the award of a Medal, and it shall be afterwards ascertained that he has gained it by exhibiting plants not *bonâ fide* his own property, or that of his master such award shall be cancelled, in favour of the Exhibitor next below him, whose Medal shall in like manner be transferred to the person immediately following him in the award, and so on

SUBJECTS OF EXHIBITION —These will be divided into Classes as explained further on No articles not of Horticultural produce will be allowed to be placed upon the tables Exhibitors will do well to make themselves acquainted with the arrangements described in the following List, as they will in ALL CASES BE REQUIRED TO SIGN A PRINTED FORM OF DECLARATION TO BE FURNISHED TO THEM IN THE GARDEN, stating under what letter their plants are to be shown; and they are particularly requested to TAKE NOTICE that if errors in the awards of the Judges should occur, in consequence of mistakes on the part of Exhibitors in filling up such Declarations, the Society cannot undertake to rectify the errors afterwards

Names fairly written are to be attached by Exhibitors to all Florists' Flowers; and the Judges are restrained from awarding any Medal to such Exhibitions, whatever their merit may be, if this regulation is not complied with By Florists' Flowers are meant not only flowers usually so named but also Auriculas Pelargoniums, Roses, and Calceolarias It is also hoped that all other subjects of Exhibition will be neatly and legibly labelled with their names

CLASS I —FLOWERS; for which Nurserymen and Private Growers exhibit independently of each other.

A Pelargoniums, in collections of 12 new and first rate varieties cultivated with superior skill, in pots of 24 to a cast GB—SG—LS

B Pelargoniums, in collections of 12 varieties, in pots of 24 to a cast GB—SG—LS

C Pelargoniums, in collections of six varieties in pots of 8 to a cast LG—GK—SB

D Roses, in pots, Amateurs to show in collections of 12 Nurserymen in collections of 25, distinct vars GB—bG—LS

N B It is the wish of the Society in a future season, to require Roses to be shown exclusively in pots, and not to admit cut specimens to be exhibited at all

E Roses in pots single specimens displaying superior cultivation bK—SB—C

F Moss Roses, in loose bunches, each consisting of three trusses as they are gathered, so as to exhibit, as far as possible, the habit of the variety, in 12 varieties SK—SB—C

G Other Roses exhibited as in the last letter, and in 50 varieties LS—SK—bB

N B No one who exhibits in this letter can also compete in the following

H Other Roses exhibited as in the letter F, and in 25 varieties SK—SB—C

N B Higher Medals than those here offered for Roses cannot be given by the Judges And if Roses are brought for exhibition without attention to the regulations here explained, they will not be allowed to compete

I Cape Heaths, in collections of 20 entirely distinct varieties GK—SG—LS

N B It is expected that the same plant shall not be exhibited on more than one occasion

K Cape Heaths; in collections of 12 entirely distinct varieties GB—SG LS

L Cape Heaths in collections of 6 entirely distinct varieties SG—LS—SK

N B No person will be allowed to show in more than one of the classes *I, K*, and *L*

M Cape Heaths single specimens displaying very superior cultivation LS—SK SB

N Calceolarias, in sizes; in pots of 24 to the cast. LS—SK—SB

O Carnations, in pans of 24 distinct varieties LS—SK—SB

P Picotees, in pans of 24 distinct varieties LS—SK—SB

Q Pinks, in pans of 24 distinct varieties bK—SB

R Ranunculuses, excluding Turbans, in stands of 12 distinct varieties for Private Growers, and 24 for Nurserymen LS—SK—SB

CLASS II —FLOWERS, for which all persons are admitted to equal competition.

S Stove or Greenhouse Plants; in collections of 40 plants. LG—GK—GB

N B Calceolarias Fuchsias, Orchidaceæ, and Pelargoniums to be excluded from *S, T, U* and *R*

T Stove or Greenhouse Plants; in collections of 12 plants, SK—LS—bK

U Stove or Greenhouse Plants; in collections of 6 distinct species LS—bK—bB

V Greenhouse Azaleas; in 12 distinct varieties GB—SG—LS

W Greenhouse Azaleas, in 6 distinct varieties SG—LS—SK

N B No one can show in both classes of Azaleas.

Z Stove or Greenhouse Climbers; in collections of 6 species SG—bK SB.

Aa Exotic Orchidaceæ; in collections of not fewer than 20 species LG—GK—GB

N B Exhibitors cannot show in more than one of the classes *Aa BB* and *CC*

BB. Exotic Orchidaceæ; in collections of 12 species GK—GB—bG

CC. Exotic Orchidaceæ; in collections of 6 species. GB—SG—LS

DD Scarlet Pelargoniums; in 6 distinct vars. LS—SK—SB.

EE. Pelargoniums, in 6 distinct varieties. SG—LS—SK.

N B By the word species is meant the wild kinds imported from the Cape of Good Hope, or New Holland, tuberous species inclusive, and not garden greenhouse

FF Achimenes, in collections of 6 species, grown in pans not less than a foot in diameter. LS—SK—SB.

GG Distinct varieties of Tall Cacti in flower. GK—SG—LS.

N B The GB and SG Medals are not to be given if fewer than six varieties are exhibited

HH Fuchsias; in collections of 12 truly necessary varieties, of which one-half shall have a light tube. LS—SK—SB

II Cineraries; in pots, in collections of 12 distinct varieties. SK—SB—C.

KK. New or extremely rare ornamental Plants SG—LS—SK.

N B These classes will be awarded by the Society's Officers, and not by the usual Judges. Exhibitors will particularly observe that none but new or rare plants can be exhibited under this letter. *Nothing will be regarded as one which has been exhibited in the Garden in a previous season.*

LL Single specimens of very superior cultivation. SG—LS—SK

MM Miscellaneous subjects SK—SB—C.

N B Exhibits under *MM* will not be thereby entitled to a pass-ticket Nosegays, Mantlepieces, Epergnes, and bouquets are altogether excluded from exhibition.

NN. Seedling Florists' Flowers. SK—SB—C

N B Every seedling must be shown singly, and marked with the name it is to bear The same seedling cannot gain a prize more than once in the season Pelargoniums are to be shown in pots, and not in a cut state No person will be allowed to exhibit more than 6 seedlings at each meeting. Exhibitors under this head will not be thereby entitled to a pass ticket. For seedling Pelargoniums exhibited the first year no higher prize shall be given than a Certificate, and this is to be awarded to flowers of decided merit Seedling Pelargoniums of the second year must be shown in pots not smaller than 32s, and each exhibitor may produce six of them, but not a larger number

IN ADDITION to any Medals assigned to the classes *I, K, T*, and *AA*, the SK SB, and C are offered for the collections in those classes which shall be best named by the Exhibitor.

N B The Society's Officers, who will make this award, will be guided in their judgment by a consideration not only of the correctness of the names but of the accuracy of the spelling, and the neatness of the writing

CLASS III.—FRUIT, for which Market Gardeners, Fruiterers, or persons in the habit of regularly supplying the Market, and Private Growers, exhibit independently of each other

N B All Fruit must be FULLY RIPE and WELL COVERED and PROPERLY NAMED by the Exhibitor as far as practicable; if the contrary it will be disqualified

OO Miscellaneous Collections of Fruit, consisting of at least three different kinds, Peaches and Nectarines being considered as only one kind GK—GB—LS

N B —Cucumbers, Tomatoes, Gourds and similar Kitchen Garden produce, are excluded from this letter.

PP Grapes SG—LS—SK—SB

QQ Pine Apples bG—LS—SK—SB.

RR Peaches or Nectarines, in dishes of six specimens SK—SB

SS Other kinds of Fruit bK—bB—C

JUDGES —The Judges have the power of *increasing* or *diminishing* the number and value of the Silver Medals offered by the Society for particular objects, and also of *conferring* Silver Medals or Certificates in cases not contemplated in these regulations, if they think it necessary to do so.

The Judges are also required to bear in mind that the Society's Medals are offered less for new and curious objects than for fine specimens of Horticultural skill, the design of the Council in instituting these meetings being not so much to encourage the Collector as to reward the skilful Gardener They are also not to make any award in cases where the objects exhibited do not appear worthy of a Medal, otherwise a bad single exhibition might obtain a prize, merely because there is no better exhibition of the same class to oppose it.

By order of the Exhibition Committee, JOHN LINDLEY,
Aug 31, 1844 Vice Secretary.

*** Copies of these Regulations can be procured upon application at the Society's Office, 21, Regent street.

TO GENTLEMEN BUILDERS, NURSERYMEN, & OTHERS

NURSERY STOCK, KING'S ROAD, CHELSEA

MR. KIRKE respectfully begs to announce that he has received Instructions to Sell by Auction, on the premises, (late the American Nursery) King's Road, Chelsea, on Wednesday, September 11th, at 11 for 12 o'clock, by order of the proprietor the ground being required for other purposes, the Valuable Collection of CACTUSES, GESNERIUMS, CAMELLIAS, ORANGE LEMON, and CITRON TREES; ALOES, FUCHSIAS YUCCAS CHRYSANTHEMUMS, AZALEAS, and SUCCULENT PLANTS; the whole in pots, and arranged in small and large lots to suit the convenience of purchasers; GREENHOUSES, &c &c —May be viewed two days prior to sale. Catalogues had on the premises of Messrs DIXON and Co, Covent Garden of Messrs P. and C LOCKHART, Seedsmen and Florists, Cheapside, City; and at the Offices of the Auctioneer, 29, Brompton row, Brompton

TYDDEN, FIVE MILES FROM DOVER.

FOR SALE BY PRIVATE CONTRACT.—Three Hundred and Four Acres of FREEHOLD, and One Hundred and Ninety four Acres of LEASEHOLD LAND, together with the Rent charge in lieu of Rectorial Tithes, over the parish of Lydden.

The FREEHOLD comprises, with Farm Buildings—

	a.	r.	p.
Coolinswood Manor Farm (Arable Land)	109	3	4
Warren Farm (Arable Pasture, and Woodland)	117	2	30
Folly or Bell Farm (Arable and Pasture)	71	0	0
Cannon Land (Arable and Woodland)	5	1	36
Total	304	0	1

and Nine substantial Cottages and Gardens

The LEASEHOLD consists of—All that capital Farm-House, Lydden Court with ample Farm Buildings, in a good state of repair, and One Hundred and Ninety-four Acres, 1 Rood, of Arable, Pasture, and Woodland, with a Rent-charge in lieu of Rectorial Tithes, valuable under the Act for the commutation of Tithes, together with a like Rent-charge over the remainder of the parish of 317a., subject to a like variation.

The Land is in a high state of cultivation There are Thirteen Years unexpired of the Leasehold

For Particulars, and to treat for the Purchase, apply to Mr COLEMAN, Kennardy Court Farm, near Dover

NEW LYNDLEY SEEDLING CINERARIUMS.

WILLIAM E. RENDLE has much pleasure in intimating to the Nobility, Amateurs, and Trade the following new varieties of CINERARIUMS raised by R. B. Lynch, Esq., the entire stock of which he has succeeded in obtaining.

[illegible] each 2l. 1s.
[illegible] " 1 1
[illegible] " 1 1
[illegible] " 1 1
[illegible] " 1 1
[illegible] " 1 1
[illegible] " 1 1

The whole set in three for six guineas; [illegible] discount to the trade.

"Rendle's Alice" has received two first-class prizes in London, "White Perfection," three prizes at Hackney, and "Rendle's Gold Medal" at Plymouth, "Rendle's" is exhibited at the Adelaide, June 20th, 1843. They all [illegible] and can be highly recommended to [illegible] after flowering.

W. E. R. has been induced [illegible] these at prices considerably lower than [illegible] for such valuable varieties, in hopes thereby to create [illegible] demand. Descriptions can be obtained on application.

Orders will be executed in their [illegible]. Plants will be delivered in October next. Guineas or remittances required from unknown correspondents. Plants will be added to compensate for [illegible].—Union Road Nursery, Plymouth, Sept 6

The Gardeners' Chronicle.

SATURDAY, SEPT. 7, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

SATURDAY, Sept 14 Royal Botanical 4 P M
Tuesday, Sept 17 South London Floricultural 1 P M
COUNTRY SHOW—Wednesday, Sept. 11 Tottenham 2 P M

THE decision of the Horticultural Society as to the subjects for which medals are to be offered at the EXHIBITIONS IN THE GARDEN next year will be found in another column. It has been arrived at after a careful consideration of the subject, and of the suggestions of many persons taking an interest in those meetings.

The main differences between the present schedule of prizes and that of last season consist in the following particulars:—

Several new classes are introduced; viz, Roses in pots, Cape Heaths in 12s and as single specimens, Ranunculuses, Stove and Greenhouse plants in 12s, Orchidaceous plants in 12s, Scarlet Pelargoniums, Pelargoniums as species, and Achimenes.

The large collections of Stove and Greenhouse plants are made to contain more plants; but Heaths, Azaleas, Rhododendrons, and Cacti, are again admitted into them, it having been found by experience that gardeners cannot make up such collections without the assistance of those kinds of plants.

Medals of higher value than before are offered in some of the classes. The Large Gold is offered for the best large collection of Stove and Greenhouse plants; two Gold Banksian Medals are offered for Pelargoniums, instead of one, and the Gold Knightian is offered for Heaths, instead of the Gold Banksian. Upon the whole, the increase in the general value of the medals may be judged of from what has been done with respect to those of gold. In 1844 there were offered fourteen gold medals, of the value of 128*l.*, for each Meeting; in 1845 their number is nineteen, and their value 177*l.*

Rhododendrons in pots, single Orchidaceous plants, and plants in Ward's Cases, no longer make separate heads of exhibition.

The declaration as to whether plants have been previously exhibited, is not to be required in future.

A new regulation has been introduced in the following words: "If any exhibitor shall obtain the award of a medal, and it shall be afterwards ascertained that he has gained it by exhibiting plants not *bonâ fide* his own property or that of his master, such award shall be cancelled in favour of the exhibitor next below him, whose medal shall in like manner be transferred to the person immediately following him in the award, and so on." This has been rendered necessary by the system of borrowing plants for exhibition, which some persons are said to have practised elsewhere this year with considerable success—a practice most disgraceful to the parties concerned in it, and such as no man with a grain of honesty would be guilty of. Gardeners have now only to look sharp after such men, whose names are in our possession, and who are well known; and if their tricks pass current in the Garden of the Horticultural Society they will be more cunning than we take them to be.

When we first proposed to Gardeners that they should turn their attention to the cultivation of Roses in pots, we were met by a cry on the part of a good many people, that the thing could not be done; that Roses would not grow well in pots; that they could not be carried from place to place; and other foolish objections of the same kind. Experience has, however, shown that the thing can be done by men having sufficient skill and patience, and the clamour of opposition has died away. Now, indeed, could any man again talk of the impossibility of growing Roses well in pots, after the beautiful displays of them made at the London Exhibitions of the last season?

That there are difficulties in the way of this cultivation is doubtless true: it was that very circumstance, indeed, which led to its introduction. There would have been no credit in producing plants which every bungling gardener could grow; but it was a great triumph to do that well which demanded unusual knowledge of the principles of horticulture. Of course in this as in all other branches of cultivation, a good many mistakes were made in the beginning, and experience was only gained by degrees; for there are things which no general principles can anticipate, and for which we are constrained to trust to practice; not that they are contrary to established laws, but because we do not know how to apply the laws of nature correctly. For this reason he who, having himself overcome preliminary difficulties, volunteers to communicate the result of his experience to others, does the community good service, and deserves encouragement; for he saves his neighbours from the errors into which he himself has fallen. We, therefore, think it a simple act of justice to Mr. Wm. Paul, of Cheshunt, to mention that he has lately published a very useful little treatise* on the Pot-culture of Roses, which all gardeners will find it worth their while to procure. We shall not make extracts from that which everybody should study in the original. Mr. Paul's extensive practice, and well-known skill as a good cultivator, will insure to his precepts the attention they deserve.

There is, however, one thing that we feel called upon to notice. In giving lists of the Roses which are to be preferred for pot-culture, brief descriptions of the colours are uniformly added. This practice, which has been employed by Mr. Rivers and a few other nurserymen in their sale catalogues, cannot be too much commended. But such descriptions, to be quite as useful as they may be, should contain some information as to the habit of the varieties; for mere colour, in plants like the Rose, is by no means all that a buyer wants to be apprised of. We could therefore have wished that Mr Paul had introduced the manner of growth into his useful little publication.

As to sale flower-catalogues, consisting merely of names and prices, we do trust they will soon be numbered with the things that *were*.

There is now such a host of so-called varieties, that it is impossible for any one, except those who have seen the plants in flower to make a selection with any degree of certainty as to what the result may be. Kings, Queens, Prince Alberts, and such charming names as Buyckii, Smouti, Merghelynchii, Canterburyensis, Altontowensis, and Sickmanni, together with the long muster roll in which eximia, splendens, superba, magnifica, grandiflora, and *omne quod exit in issima*, cut so conspicuous a figure, convey no idea of the merits of plants or of their colour, whilst a very short description, not exceeding the extent of the line on which the name stands, would enable every one to exercise his own judgment in giving his orders. This observation applies to all florist's flowers, as well as to Verbenas, Fuchsias, Pelargoniums, Calceolarias, Petunias, and the like.

Of this we can entertain no doubt, that those nurserymen who adopt the plan, will carry off their customers from those who do not. They, too, may count upon the largest number of orders who, in preparing their catalogues, show the greatest desire to inform their customers of the true qualities of the plants they deal in.

Some weeks ago we expressed our willingness to print a form, which, when filled up, would explain the actual condition of any Horticultural Society; and we expressed a hope, that if a considerable number of such forms were filled up correctly, the comparison of them would throw light upon the true cause of the prosperity or adversity of the numerous local associations of this kind.

We have now to announce that these forms, of which the following is a copy, are ready for delivery, and will be sent to any one who may express a desire to have them.

HORTICULTURAL SOCIETY OF ———

When established
How many exhibitions annually
——when and where held
How many and what classes of exhibitors
Average amount of income
——from what source derived
Amount of subscription to constitute a member

* "Observations on the Cultivation of Roses in Pots; in whatever Forcing and Fumigations, with a List of Varieties best suited for Pot Culture." By Wm. Paul. 12mo. Sherwood and Co. 35 pages.

† If the Society is not flourishing, the probable cause of its want of success, such as want of funds, clashing of rival Societies in the neighbourhood, jealousies among exhibitors, dissatisfaction with the Judges, disputes among the Managers, &c. &c., should be stated.

We earnestly invite the secretaries of local Societies throughout the United Kingdom to co-operate with us in this work, which we trust and believe is capable of producing some solid advantage to the great cause of Horticulture.

MANY PERSONS PURCHASING PLANTS from what is generally advertised as "Dr. Lindley's opinion," are disappointed when the blooms appear in their own collections. It is worth while to inform the public that such opinions as appear in the *Gardeners' Chronicle* under the head "Seedling Flowers," are formed upon single blooms forwarded to the office. It is, therefore, very unjust to charge the disappointment purchasers may meet with to the account of any other than the party forwarding the blooms. Our recommendation is not to purchase except from a report upon the plant itself. A *really good thing* will always pay for the expense of appearing in that state. We have before us now a *border*-flower which in the greenhouse is everything it was stated to be in "Dr. Lindley's opinion:" out of doors it is really worthless.—*B.*

SUCCULENT PLANTS.

THE following is written with a view to draw more of the public attention to the cultivation of succulent plants. No group offers more facility for almost universal distribution, and every dwelling can have a few species in healthy, vigorous growth, and beauty of bloom. The humblest cottage-window may be enriched by their pleasing flowers, or made interesting by their curious forms. In the town of Cove, near Cork, the Fig-Marigold is as common as Stone-crop; hung up against the small shopkeeper's window is the Mesembryanthemum inclaudens, with its pinky-edged green leaf and purple rose-coloured blossom, shining in the light for weeks in the early summer, and gratifying the eye and taste, as well as the pleasing feeling of the owner, that under his or her protection a living creature flourishes and blooms. The M. bicolor is there too, and the silky-blossomed M. blandum, with others whose names are not easily traced for want of accessible illustrations of the family. I mention these circumstances, because the means to have these flowers is so inartificial, that many may give them a place in their attentions who are not aware of its facility, from the broken jug, teapot, or teacup, down to the very eggcup, the Mesembryanthemums are located in Cove, and all they require for some progress is light, and not to be too much watered in wintry or in cloudy weather. I do not recommend this treatment as the best, but it shows the endurance of many of the species, and invites to extended trials of what may be done in making them more general among the community. But to bring the succulents more under cultivation, so as to make them objects of interest to the florist, some aid is required. An accessible monograph of illustrations is much wanted, as the descriptions in systematic works cannot be popularly understood so as to determine the kinds, except they be accompanied by figures.

To know the names of the objects we care for, increases, because it individualises and appropriates our regard; and for this reason we desire to distinguish one thing from another, but more, we may be giving space in our rooms, and our care to plants which rarely bloom, to the exclusion of more grateful companions, who would, if domesticated, constantly express their thanks by throwing their smiles upon us. I have been trying the adaptation of circumstances to them in the open air. As to "acclimatisation," I do not believe in it. The M. aureum, planted in a hole in a wall, grew out and flourished and bloomed well for two years; rain, however, in the winter of 1842, swamped it to death. I obtained a series of species, which I potted in gravel and earth; I had all well struck and placed on a demi-wall facing the east, but the drip of an Ivy hedge blocked them in the autumn, and they became the favourite food of numberless devourers, "both those that crawl and those that fly." I was, however, quite successful with those which I put in an old window of a turret in the open air, the shelter being merely the depth of the "reveal," about nine inches or so; I covered the window stool with coarse gravel, kept together by bricks at the edge, and partly in pots and some in clumps turned out, I have my "blind window" an object of admiration. In winter a little coarse rubbish is a good great-coat for these things, but they must have sufficient drainage, or they are gone.

Drainage at the root being made certain to insure vigorous growth, these plants may be copiously syringed over the head every bright day in summer, and once a week in spring and autumn, in winter they need not be watered at all. I have now a series of Mesembryanthemums on trial as to their winter behaviour in a state of liberty, and I hope these Africans will show themselves worthy of freedom in our climate, although new to them. My preparation is this:—I have made holes fully twelve inches deep, and filled them with large clean river gravel, into this I have turned my rooted succulents, and then, having drawn the peat over the top, left them to our sunshine and showers; what they may do in the winter, time will tell, but their beauty now is most striking—they have made magnificent leaves, and M. blandum, the only one which has blown as yet, is a great beauty; indications is coming out, and promises very well, but the leaves or fronds on various species are so altered in hue, in depth of shining verdure, and crystalline encrustment on those "who wear diamonds," that a person would scarcely know them; they now

differ far more from their forms when imprisoned in pots than many species do from one another. In these felicitous Post-office times such tenacious-lived plants may be sent everywhere. A card pen-box with a bit of wood in it to prevent the stamp from crushing it, would carry three or four species for a postage of as many pence; and if the kinds were well described, the prices of them would soon be published. I have no doubt that curious and valuable hybrids might be raised from seed; and if the gravel and peat do well, we are only beginning our exotic civilization. Noland prostrata, and many fleshy-leaved plants, or other groups not called succulents, enjoy this treatment extremely; but even if we are driven by the rain of winter, to keep our plants succulents within doors, we cannot do well without an accessible index to them. In fact, the Mesembryanthemum, which has grown down the wall out of its sheltering alcove, has borne last winter well, and has blown a perfect sheet of dazzling purple bloom for nearly all the summer—must have its worth unrecorded for want of knowledge.—*R., County Cork.*

ON THE PRESERVATION OF FRUITS.

Amongst the different materials for preserving fruits, recommended by different authors, are found the following:—Charcoal, Sand, Moss, Oat chaff, the Husks of different Grains, Oats, Sawdust, Paper, Bog-mould, Beech and Hazel Flowers, Bran, Canvas, Sealing-wax, Hay, Straw, and Fern.

The Husks of the different varieties of Corn, as Oats, Barley, Wheat, have been by some recommended for keeping fruit in; but I disapprove of them, on account of the obnoxious gases they absorb during the process of kiln-drying; before being ground, however, these, as well as Oat-chaff, answer well for packing, if the fruit has been previously surrounded with fine paper or linen, dried before the fire previous to being used.

Oats.—I have been informed that in Portugal Apples and Pears have been preserved the whole year round by being packed in air-tight vessels and surrounded with Oats, which received no injury by being in contact with the Apples. This material is not, however, generally used for packing, as the grains of the Oats are apt to bruise the Apples.

Sawdust.—This should never be used, except it can be procured from hard-wooded trees, such as Oaks, Beech, &c. The sawdust of resinous trees should on no account be used for this purpose, as it is never entirely free from a resinous smell, which gives the fruit a disagreeable flavour; it might, however, be used for packing fruits in, that are to be sent to a short distance, but each fruit, previously to being immersed in the sawdust, should be well surrounded with linen or paper.

Paper.—This material is employed for preserving fruits, but it becomes expensive where there is a large quantity to be preserved. If charcoal or sand are used, this and all other covering may be dispensed with.

Bog-mould.—I have been informed that this has been tried for preserving Apples during winter, and that it is found to answer the purpose; but having little experience with it, perhaps some correspondent that has used it will favour me with the results.

Beech and Hazel Flowers.—I can recommend the use of these for packing and preserving fruits, especially the more delicate kinds. They answer well for packing Grapes, Peaches, &c., first putting in a layer of the flowers, and then a layer of Grapes, or Peaches, until the box is full; the fruits will be found as fresh at their journey's end, as when first put in, with the exception that the bloom of the Grapes will be destroyed. However, it may be renewed by dusting fine flour over the berries, holding the bunch by the stalk, or stem, during the operation. Beech and Hazel flowers can easily be procured; they should be collected soon after they have fallen from the trees, and put into an airy room to be thoroughly dried before they are used.

Bran.—When this material can be procured, it will, perhaps, answer equally as well as the former; and being of a finer nature, it will more readily fill up the crevices between the fruit.

Canvas.—This material has been strongly recommended by some, with a view to prevent any dust from settling on the fruit; it also tends to prevent their evaporation, by preventing the air from acting on them.

Sealing-wax.—This is much employed in France, and other parts of the continent, for preserving Pears. It is applied by melting it at the end of the wick as you would seal a letter, only not putting quite so much on. In this way fruit is preserved for months.

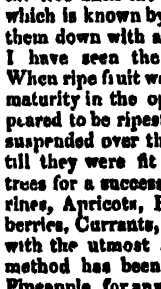
Hay, Straw, and Fern.—These have been used for a long time, for covering Pears and Apples in the fruit-room, and likewise for packing; and I consider them coarse for packing, when other materials of a lighter nature can be procured.

Pitting.—Apples may be kept in pits after the manner of Potatoes; we have seen this practised both in France and England with success; but the fruit does not keep long after it is taken out; consequently, only a small quantity should be taken out at one time, and the pit should be instantly closed up, to prevent the admission of air. Apples kept in this manner will be found quite sound and good in the months of May and June, or even July, if they have been pitted in a careful manner, all bruised ones being rejected, which would destroy the others. A little powdered charcoal should be carefully sifted over the Apples as they are laid up, which should be done in regular layers. The charcoal absorbs any moisture that is given off by the Apples, and keeps all cool. After this is done, take some clean Wheat-straw, or Hay, and lay it over the fruit, to the thickness of a foot, fastening it down with rope mats of the same material, then cover them up with earth to the depth of another foot. This covering will prevent any change in the atmosphere from reaching the Apples. The operation should be performed in dry weather.

Preserving fruits on detached shoots has been adopted, but with little success. The experiment was tried with Grapes, which were detached from the main branch, a piece of the shoot, about a foot long, being cut with the bunch. Some were immersed in bottles of water, others were suspended in the fruit-room, and part was left on the shoots in the Vinery. It was found that those in the Vinery kept as long as the others. A good plan is to cut the bunches, and turning them upside-down, suspend them in a room with a steady temperature a little above 32°. Another method is to cut off the bunches, with a foot of the stem on each side of the bunch, sealing up the cut ends with sealing-wax, and suspending the bunches at the above-mentioned temperature. The following is a good way of preserving ripe Grapes:—Procure some tin cases of any convenient size, and put in a layer of dry sand or charcoal and then a bunch of Grapes, until the case is full; seal down the lid and make all air-tight, and bury them to any convenient depth in the ground. This plan will likewise answer for late Cherries, Plums, Gooseberries, Currants, &c. These fruits in some gardens are retarded in their time of ripening, by being covered with mats or nets, which is an excellent plan, and ought to be more generally adopted, as it insures a succession. Grapes, Peaches, Apricots, in the open air, may be kept for some time hanging on the trees after they are ripe, by the same means, but their flavour will not be good. Red and white Currants in the same manner will even keep good till the end of December. Ice-houses have been recommended for preserving fruits; but they are objectionable, on account of the damp moisture which they contain. A dry, cool, and airy room, free from all atmospheric changes, is the only place where fruits can be preserved for any length of time.

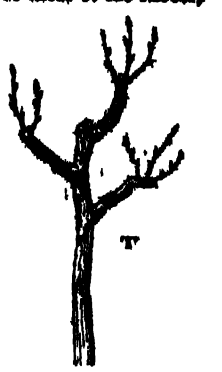
It will be found that some of the finer sorts of Pears and Apples are liable to crack before they are quite ripe; therefore they should always be gathered and taken into a hothouse, in order to ripen them as quick as possible. It often happens that one half cracks while the other remains sound. Those that are sound should remain on the tree until the proper time for gathering them arrives, which is known by gently lifting them up, and then letting them down with a slight jerk; if ripe, they easily detach. I have seen the following plan adopted with success:—When ripe fruit was wanted before it had arrived at proper maturity in the open air, those were selected which appeared to be ripest; they were placed in a hot-house, and suspended over the hottest part of the flue, in a basket, till they were fit for use; the remainder was left on the trees for a succession. The ripening of Peaches, Nectarines, Apricots, Plums, Cherries, Strawberries, Gooseberries, Currants, &c., may be accelerated in this manner with the utmost advantage. I am not aware that any method has been adopted for the preservation of the Pineapple, for any length of time. I have seen it cut up and immersed in bottles containing spirits—as brandy, whisky, &c., to which it imparts a pleasant and delicious flavour; Plums, Cherries, and Apricots, are used for the same purpose in France.

The sweating of Apples is not to be recommended, as the flavour of the fruit is much deteriorated by it. The less fruit is handled the better; and the less it is exposed to atmospheric changes, after being gathered, the longer will it remain plump and sound, without becoming dry and mealy.



Green Fruits—For preserving, must be gathered when quite dry. Having provided some wide-mouthed bottles, or tin cases, commence by cutting off the berries, one by one, from the stalks till the bottles are full; cork them up tight, and seal them over with some wax, then place them in some cool, airy room, or, what is better, plunge them into the open ground, surrounding each bottle with some charcoal, or dry sand.

Shell Fruit, as Walnuts, Nuts, Chesnuts, &c., may be preserved for a year or two by being divested of their outer shell, and thoroughly dried. In jars, or tin cases, put in a layer of charcoal or dry sand, then a layer of Nuts. Proceed in this way until they are full, properly securing each lid, to prevent the admission of air; when finished, bury them in the open ground, or in some cool and dry cellar.—*J. McIntosh.*



THE ROSE-GARDEN.—No. XVII.

(*Continued from p. 572*)

Shape of Trees.—A tree well formed, with a promising head, and in health, ought, the spring succeeding the budding, to have a clean, straight stem, no lumps nor knots, one shoot quite at the summit, and two, or at all events one other shoot as near as possible also to the top; if there are two shoots only, at opposite sides to each other; if three, forming a triangle; if more, as nearly equidistant from each other, in the diameter of the stock as possible (and here be it observed that the more shoots, at the top of the tree, the handsomer and quicker is the head formed,) each with a bud inserted in it, close to the stem; and at the cross cut, where the back of the bud usurps the place of the original bark of the stock, a sufficiency of sap ought to have exuded, not only to have joined the back of the bud with the unmoved part of the bark above it, but also to have joined the separated part of the bark of the stock to the same place, and thus linked the two barks of bud and stock to the single bark of the stock above them.

The edges of the vertical slit in the bark do not heal by attaching themselves to each other, but the bark of the bud underneath them forms a connecting link, and the edges above mentioned perish insensibly away, leaving little or no scar behind. The second spring, the tree becomes more perfect, the extraneous parts of the stock, if any remain, are cut off, as well as those of the shoots, and the head so arranged as to throw its buds where they are wanted to make it round, even, and handsome. If, however, some shoot be obstinately bent on growing in any direction, spoiling the appearance, and crossing the others, it should by no means be removed on that account alone; but if a little twig be placed across from it to any other convenient branch, to confine it for the season in the place desired, the ligature may be removed in the succeeding spring, or even in the same autumn, when the sap is down, and the shoots preserved.

T. In order to keep them distinct and clear, the annexed cut shows the shoots at a much greater distance from the stem than they will in reality be, the buds they spring from having, as before-mentioned, been placed as near to it as possible.

Lastly, the third spring the tree should show itself with all its wounds nearly closed, its buds strong, full, and healthy, and it should look perfectly natural, those parts of the shoots upon which the buds were placed being incorporated with the stock. The bark clean; no dead wood; and wherever a shoot has been shortened, the place so grown over as to leave no blemish, which will be the case for some time wherever any wood more than one season old is cut away, and a thin shoot of a single year springs at the end of it. This is the reason why forest-trees look so ill if shortened when old, viz., the taper appearance is destroyed, wood of five or six years' growth is continued by the shoot of a single spring, and thus a piece of wood, of the diameter of half a dozen inches, has a little mean-looking shoot, or in all probability half a dozen, not thicker than horsewhips, at the end of it.

Whatever it is worth while to do, it is worth while to do well; work properly commenced does not require that constant superintendence which a bad beginning is certain to render necessary, and which eventually involves a much greater expenditure of time than any labour bestowed at the outset could have demanded.

Home Correspondence.

Provincial Horticultural Societies.—Your remarks on these, p. 499, are well-timed. All country societies of the kind move, as it were, by fits or jerks; and there will, of course, be no permanent cure for this fitfulness until we are well acquainted with the causes. I have attended many Shows of the kind for the last 10 or 12 years, sometimes as exhibitor, and frequently as judge; and have therefore had a little experience in the matter, the result of which I hope may be of service in the investigation. Fashions, we all know by experience, will change; therefore I am afraid it is useless to expect that the public will long patronise one set of objects, however dazzling their appearance or high their cultivation, without relief of some kind. This seems to point out a necessity for variation in the objects of societies, year by year; which change, of course, rests in a very considerable degree with the respective Councils. Now, without wishing to cast any imputation on any given society (a thing I will endeavour studiously to avoid as quite foreign to the purpose), I must say that the Councils of provincial societies are frequently very inefficient in character, as to the objects sought to be attained—viz., thoroughly satisfying that portion of the public which possesses a more refined taste, and so remunerating the various grades of exhibitors as to send them home satisfied, and eager to show their faces at the next meeting. Now, whence the inefficiency complained of? A spring meeting is convened to arrange the future campaign; the Council meet, and instead of being composed of one-half practical gardeners, is chiefly made up of tradesmen and mere florists, who care little for the progress of general horticulture: the former esteeming a huge Cauliflower or Cucumber, and the latter a bed of Tulips, to be the *ne plus ultra* of all gardening. Something more definite should be observed in regard of these Councils, especially as to the number of their members. They are generally too few in number; there should be seven at the least, in my opinion, which might be thus constituted:—two respectable tradesmen; two florists or amateurs of good standing; three general gardeners; at these meetings, the general awards should be classified distinctly as to what portion of the funds should belong to the amateur, what to the florist, what to the general gardener, and also the cottager; last, though not by any means least, a proper arrangement of the mode of competition; for it is found in gardening as in horse-racing, that if the company is too good there is small chance of competing with success. The secretary should, by all means, be a paid officer—what is done without stipend, is sometimes half done, and much depends on the secretary's punctuality and courtesy in taking care to make all parties, more especially subscribers, acquainted with every move of the society, so that nothing appear to be done in secret. To this end I

would have a balance-sheet of the state of the society's funds, posted at every meeting at the corner of the show-room, with an invitation appended to it, for those subscribers who felt inclined, to examine the secretary's books in to the details, after the business of the day had passed by. There is no small difficulty at country Shows in obtaining good judges, gardeners who are exhibiting in several classes being by no means eligible; and few gardeners are so well off as to travel a distance of twelve or fifteen miles at their own expense, and give their services gratuitously into the bargain. The consequence is, that very frequently incompetent judges are selected, and if a first-rate gardener happens to be joined to them, he has it all his own way, and the others are reduced to mere automatons. Much difficulty exists in getting the subscriptions—this is shameful, but it is too true. A good plan, in my opinion, would be to collect the subscriptions very early in the spring, and to state in the circulars that no other would be considered available to the purposes of the current year, than what were received by an appointed day, soon after which the arrangements would be completed, and the subscriptions published in the county newspaper. It is customary to charge a small sum at the doors for visitors inspecting the rooms who are not subscribers this is, in many places, not adhered to so strictly as it ought to be. The door-keeper should be a stranger to the neighbourhood if possible, and have strict orders to exact the sum appointed from all who did not possess tickets. The chief cause of failure, however, is want of sufficient funds—the conductor of these meetings has, in most cases, one of his hands tied. There is a good deal of expense incurred in the mere machinery of such meetings, and after such is deducted from these cramped subscriptions, the rest is obliged to be cut out into such meagre prizes, that few but those who are independent, care to compete for them: ninepenny and eighteenpenny prizes are by no means uncommon at the country Shows, and many a poor wight goes home with a half-crown in prizes, who can ill afford to pay his travelling expenses. There can, therefore, be no permanency or strength in these societies, until the amount of subscriptions is considerably improved. The above facts, though not applicable to the great metropolitan societies, are, I am well assured, to many of the provincial ones.—*Argus.*

Pelargoniums.—I have had some of my plants change on the edges of the leaves like the inclosed, giving the plant the appearance of a variegated sort. The leaves appear quite healthy, with a regular pale border, which is principally confined to the old leaves. The only thing I can suppose it to arise from is, that some time since I had the Pelargoniums watered with sulphate of ammonia, which had been exposed to the air for some considerable time, and had become quite fluid; and it is possible that it might have been partially decomposed, and a free acid (sulphuric) left, which we know has the power of bleaching vegetable colours.—*H. Groom* [This is a curious case. The leaves have a pale border, about ¼ inch deep, as regularly limited as if it were really a permanent variegation.]

The Robin and Hedge Sparrow.—It is my misfortune to live in a large town, so that, when at home, I see none of the feathered race except that bold, impudent, sooty, but withal comical fellow the house-sparrow. My small garden is some half mile off in the suburbs, and I do all in my power to induce the birds to frequent it, though, as an incessant warfare is kept up against them by every "idle apprentice" who can lift a gun, they are far from numerous. I formed this garden in the winter of 1836, and immediately a robin took up his quarters with me in the greenhouse, going out during the day, and returning at night to his roost in some of the shrubs therein. I was at first puzzled to find out how he got in, till I noticed that a triangular piece of glass had fallen out of one of the small panes in the roof, which are three inches broad, and saw him enter by alighting on the edge of the pane below, stoop his head, hop through the hole, and expanding his wings fly to his roost. Of course he could not get out by that opening, and therefore on entering the house every morning I gave him the option of making his exit for the day, which he generally did at once. If, however, the weather was stormy, or a keen frost or snow was on the ground, he used to return in a few minutes with all his feathers standing on end, and very intelligibly, though mutely, beg for admittance to his old quarters, where, having plenty to eat and drink, he spent his time in watching my movements, or hunting about amongst the plants. In very cold weather he prefers a stove heat, and should I leave the door leading into it from the greenhouse ajar, I am sure soon to find him after me. When there he appears to enjoy himself much, he gathers his puffed out plumage tight about him, and looks as he does in summer-time. His large, beautiful, intelligent black eye (only equalled by that of the nightingale) is in constant watch of my motions from his usual perch upon the suspended orchidaceæ, or the rods intersecting the roof from which they are hung. In this manner he has passed every winter since 1836, returning to his quarters about November, and leaving them in February or March. He has now become so tame that he feeds from my hand, and when perched thereon sometimes amuses himself by picking out any crumbs, &c., that may have lodged underneath my finger nails when preparing his food. When in the stove, the moment he sees me enter the greenhouse he flies to the door which separates them, fluttering against the glass in his attempts to reach me, and as soon as I open the door, alighting on my hand, seems grievously disappointed if there is nothing eatable in it, although he may have plenty of food within reach. In summer he and his mate build their nest close by, and are very familiar, though they will not come to the hand. Another pair have built twice with me this season in the same mouse's hole in an old hedge which I retain in my garden, and allow any of the family to approach close to them without being alarmed, popping out their heads in reply to the challenge of a whistle to them. So tame are my young robins, that during summer and autumn it positively requires that one watch their movements to avoid injuring them when hoeing and raking, so closely do they come about one; and it is no uncommon thing for my sisters, when working amongst their flowers, to have three or four of these youngsters in constant attendance during a whole morning. The hedge-sparrow is another of my especial favourites, for I consider it the most affectionate of birds, neither yielding to the dove or the love bird in this respect. They always go in pairs, and having once taken each other "for better for worse," never separate, and seem unhappy when out of each other's sight even for a moment. They are most inoffensive, subsisting chiefly on insects and their larvæ, and ought to be kindly treated by every gardener. Two pair of them seem to consider my garden their home, as they remain with me summer and winter, building in the shrubs, and in cold weather keeping about the open sheds, &c., and coming regularly to be fed. I often stand and watch their movements upon the lawn, which they haunt over in search of insects, in that half-hop, half-flight, so characteristic of this bird, always within a yard or two of each other, and keeping up their low twittering note. Should one of them happen to get out of the other's sight, the moment it is missed you hear the call of its partner, and can see how distressed it is at its absence, whilst the well-known reply, and the delight on their meeting, almost invariably elicits the song of the male. "Bless their kind hearts!" say I, with Mr Waterton, the quotation from whose delightful work in your last has induced me to send you this.—*Pons Ælii.*

Wasps and Bees.—I have tried Professor Henslow's method of destroying wasps, and found it to answer admirably. I put a small quantity of spirits of turpentine into a bottle, and at night, when the wasps were all at home, the bottle was inserted in the mouth of the nest; a spadeful or two of puddled earth was put over this, about a foot in thickness, in order to make the work secure. My man, who had never employed anything but gunpowder and brimstone for this purpose, was doubtful about success. In twenty four hours, however, all the straggling wasps having disappeared, the nest was opened, and all were quite dead. My man said they would come to life again if he did not smash them with the spade; but before doing so he took out about a dozen of the white waxy-looking sealed up bags, containing the young embryo wasps, these were wrapt in paper and taken home, in a day or two the paper was opened, when some of the bags had been converted into mature wasps, others appeared as large moveable maggots, and some were the same as when first taken out of the cells. I have a hive of bees not far from the spot where the wasps' nest was found, and I had noticed wasps about the hive. I have watched them go into it, the bees did not appear to resist their entrance, nor did I see any symptoms of fighting. I diminished the entrance of the hives to two small holes, which are only capable of allowing one bee to go through at once, and since that alteration a larger number of bees are generally about these holes. This morning I did not see one wasp enter the hive; they came and flew about, went once or twice near the entrance, and flew away. Will any bee-keeper inform me whether or not the destruction of bees is the consequence of wasps entering the hive, or whether robbery would set by the intruders? whether or not the bees would fight them after they had entered the hive? and whether or not the diminished entrance will do any injury to the bees?—*Jasper Stokes, Birmingham.*

Gray Parrot.—I have one of this species which once suffered in the same way as a "Constant Reader's," but is now in perfect health, the cause, I doubt not, was the want of water. My pet is thus managed.—As soon as convenient after breakfast, the door of the cage is opened, and Miss Polly then mounts to the top of her cage, and there expands her wings, gives them a good shaking, and gets rid of a great deal of white dust, which, I doubt not, is dried skin. While she is thus employed her cage is thoroughly cleaned out, the bottom strewed with sifted gravel and about a tablespoonful of Hemp seed put into one side of her tin, and her cup filled with fresh water, bread or toast is soaked for a minute or two, but not made pappy, and then given to her, at dinner, or luncheon, she has a bit of meat or a bone not closely picked, but all fat or butter must be carefully removed from it; if we have a milk pudding she has her share, at tea the toast is again prepared, but in no case is more given than the bird can consume. A cup of clean spring water always stands in the bottom of the cage; but if a "Constant Reader's" polly is as mischievous as mine, it had better be fastened to the wires, my bird hangs in a large porch furnished with flowers, and more than once I have received the contents of the cup on my head or back. When moulting, a Clove or two should be put in the water, and by way of a *bonne bouche*, she has from time to time a bit of captain's biscuit. Parsley must be carefully withheld—it is most injurious to parrots. With the above treatment no bird can be in better health, more lively, or in better plumage. The "Constant Reader's" parrot should have as much air as possible on fine days, and as much liberty on the top of her cage as convenient, when in the house.—*Y.*—Miss Kenworthy, of No. 5, Russell-street, Liverpool, is so obliging as to say that, if a "Constant Reader" will send her his address, she will be most happy to give him such information as will effectually cure his bird, and restore its plumage.

Bees'-Eggs.—At p. 572, "A Lover of Truth" says—"As the queen knows when she is to lay a drone or male egg, in what way is that knowledge acquired?" Again, he asks—"Does one ovary contain male eggs only; or are they to be found in every ovary?" According to Hunter, the eggs are not contained in ovaries, but in twelve small ducts; but it is hard to say how the male and female eggs are situated. I shall, however, hazard an opinion respecting their being deposited in the cells. The queen bees differ from other insects that lay their eggs only at certain times, and that have the male and female eggs mixed together; if the season permitted, she would lay eggs to produce working bees during the whole year, and those to bring forth drones only at certain periods. Now the latter may be situated in the duct or ducts, so that they can only exist at certain periods, and the insects know of course by instinct, the proper cells for their production. It may be worthy of remark that after the queen bee has layed drones' eggs and a few to produce queens, she lays only workers' eggs; while in autumn, others of her race, such as humble bees, wasps, and hornets, rear none except drones and queens, especially the yellow pests, who often shave off the workers' cells from the upper combs as materials for forming queens' cells below. Drones are reared in cells of the same size; all this is quite in accordance with the manner in which they increase their species. In reply to the query respecting difference between the size of male and common eggs, I may state that I have fancied that the former were a shade larger, but the exact age of the eggs ought to be known, for they of course swell before the larvæ burst them. "A Lover of Truth" mentions the number of drones' eggs his queen bee lays, and also that of workers' eggs, which he says was 1000 daily for three successive months. This not only exceeds Huber's number—200 daily—but also Schirach's highest number, which is 100,000 in a season.—*J. Wighton.*

Flower Gardens.—I beg to confirm "E. C.'s" statement (p. 525) respecting the appearance of these. On visiting Marston Rectory I was delighted with the brilliant display in the flower garden; the beds, both with regard to flowers and foliage, were all that could be desired, and I was informed that they have been equally beautiful for four months past. This, taking into consideration the bleak situation of the garden, and very bad soil of which it is composed, reflects the greatest credit on Mr. Melville, who is gardener there. The other gardens alluded to by "E. C." are, and have been, the very acme of perfection. The beds are planted with the same kinds of plants that are generally to be met with in good gardens.—*A. A.*

Strawberries and Asparagus.—I beg to offer a few remarks upon the statement of Mr Bree, of Stowmarket, respecting the culture of these plants. Of Strawberries he says, that "he had such a capital crop, because he did not cut off the leaves." The discussion which took place last year about cutting off Strawberry leaves, induced me to adopt the following system by way of experiment.—Of one Strawberry bed I cut the leaves all off one half, and the other half I did nothing to; I cannot, however, speak in praise of the latter half; having other two beds both in the same aspect, I was anxious to learn from which of the two I could obtain the most fruit. From one bed I cut all the leaves and manured it immediately. From the other I cut all the runners, and left the stools entire, and then manured it, which I could easily do, as I plant my Strawberry rows 3 feet apart. The bed that I thus treated was but one year old, the other bed was three years old—that from which I cut all the leaves. I can vouch that I had quite as many Strawberries from the old bed as I had from the new one: this I did not expect, both the beds were of the same sort, viz. Elton Pine. Have any of your readers made a similar experiment? With regard to Asparagus, Mr. Bree goes on to say, that "J. Squinell killed all his Asparagus by cutting off the tops in June." This I have no doubt was the result, but, as was stated at p. 317, of this year, I imagine that salt should only be applied when the plants are in full growth. I consider that Mr Bree practised nearly as dangerous a system as his friend "Y. S." in applying salt at the time when the roots were in a state of rest. I should say that salt would be applied with more advantage in spring—say in the month of March; put it on immediately after the beds are dressed. If the weather is dry, water the beds well, previous to putting on the salt, and then 2½ lbs of salt to the square yard might be used, which I have no doubt would give great satisfaction.—*Villagius.*

Vines.—I have two vineries; No. 1 has the canes trained to the rafters, one only to each. This house is heated with hot water in iron pipes, and has besides about eight cart-loads of tan in it. In No. 2, the Vines are trained horizontally, the whole length of the house (about 20 feet), this house is also heated with the same sized pipes, but no tan is used in it. Now it so happens that this house has matured its produce better, in every respect, than the house with the tan. From what cause has this arisen? Was it the horizontal mode of training which caused it, or was there too much moisture in the tan to allow the Grapes to colour, from excessive evaporation. Heat and air were allowed to both houses in nearly the same degree. Perhaps I ought to mention that the tanless house is situated considerably higher than No. 1, to reach which the Vines are carried a greater distance

follow their fruiting habit was allowed to expand. Has this a tendency to determine the sex more than in Dic.? Perhaps some of your correspondents may throw light on this subject.—*A Subscriber, Maidstone.* [The last circumstance is probably the cause of the effect observed.]

Morphology.—It is an important consideration in connexion with this subject to know, that the proper food of plants consists of the elements of which their structure is composed; and that if a soil be destitute of those elements, no susceptible development will be apparent, so far at least as the nutritive tissue analysed is concerned. Such being the case, it naturally follows that what the stem is to the bell, the flowers and fruit are to the branches, namely, a higher structural result; or in other words, the flowers and fruit may be said to be rooted in the stem and branches, and supported by more perfect tissues than the original roots afforded. Am I correct in these conclusions?—[Yes.]

Culture of the Onion.—I beg to mention a method I have been practising for the better growth of Onions. The soil here being the worst I ever met with for the culture of Onions, forced me upon trying an experiment. Late in the autumn of last year, I caused a piece of ground to be dug deep and left in a rough state. I then procured a quantity of hog manure, which was spread over a portion of the prepared ground; at the same time I got some horse and cow manure, which were also spread separately on the remaining portions of ground. Previous to laying on the manure, the ground was well salted with common salt. I suffered the manure spread over the surface to remain through winter until April, when it was forked off and wheeled away. Onions were drawn from the seed-bed, and transplanted on this piece of ground, and the result has been as fine a crop as could be desired. Of the three kinds of manure tried, I find that the hog manure has answered the purpose best, but the Onions on all the portions are good, whilst in other parts of the garden not so prepared, they have failed, and are not worth gathering for keeping, as three parts of them are grubbed, while the piece experimented on is perfectly free from grub.—*J. L. Snow, Swindon Park.*

Long Vitality of Seeds.—Some time since a well was sunk in the Isle of Wight 300 feet in depth, and out of the earth from the very bottom Charlock sprung up. When and how could that seed have got there? The whole of the place in which I reside was, about thirty years ago, garden ground. Last year a sewer was made in the public road, and I had some of the sandy gravel laid in my garden; this spring a number of young Cabbage plants have sprung up out of the gravel, and as I have had no Cabbage-seed, they must have lain dormant and have sprung into vitality upon being exposed to the influence of light and air.—*Semen.*

Strawberries.—How do scientific gardeners account for the habit of Strawberry-plants forced under glass in spring continuing to form blossoms and fruit afterwards during the whole summer, when turned out into the open air? For many years past I have forced Keen's Seedling Strawberry by keeping it under glass from February till the beginning of May, when the fruit is just turning ripe. I then place them on a south border in the pots in front outside my Grape-house; this gives them a high flavour—even higher than those planted in the open ground. This year I had an immense crop in May from my forced pots as treated; and, finding as large a supply of blossoms the end of June, when the first crop was gathered, instead of planting them in the open ground, I gave them a watering of liquid guano, and the second crop in July was as abundant as the first in May. Mr. Markham, gardener to the Hon. R. Clive, of Hewell, came and looked at them, and expressed, with other gardeners, his surprise at the very abundant second crop. The beginning of this month, finding more blossom peeping through the leaves, I gave them another watering of diluted guano in rain-water; and a third crop is setting, and from the vigorous appearance of the plants, I expect they will go on to produce fruit till cut off by autumn frosts. How is this? We know that, with the exception of the Alpines, the other Strawberries bear but once in a summer, in the natural ground. Why should the forcing in the spring give the disposition to flower the rest of summer?—*John Wellbourn, Wilmcote.*

Nepaula Cucumber.—I beg to inform "A H," p. 573, in answer to his inquiry about this, of the following circumstances:—I had a few plant of it last year, which disappeared unaccountably at the time. I attributed it to the carelessness of the gardener or the ignorance of young weeders; I searched the border where it grew, and found a stout seedling, which I surrounded with a fence of twigs stuck firmly into the ground. It became a flourishing plant, and I gained much upon my contrivance to preserve it; but the frosts and the plants were totally destroyed not many nights after, and upon examining the plants, I found the surface of the ground where it grew completely flattened and smooth, and having a quantity of cat's hairs well pressed into it.—*J. B.*

Potter's Guano.—I have tried Potter's guano on Turnips, Cauliflowers, &c., with success. The proportions were, one fifth guano, four-fifths night-soil; on the first I spread it broadcast, and watered it well afterwards; on the other plants I removed the earth about half an inch deep round the stem, and to the extent of about six inches in a circle, and then spread a handful of the guano on the ground so prepared, and covered it over again with the removed soil. All the plants were well established before using the compost, and now appear remarkably healthy. My garden is a stiff clayey soil. Potter's guano is an expensive manure.—*Fulcon.*

Scorching Effects of the Sun.—I should think it is probable that the cause of Vine leaves becoming discoloured under the influence of the sun, after being syringed, was in consequence of the water containing some ingredient that [illegible] the water has been [illegible] from the various accounts given [illegible] all complain of [illegible] ment; I should, therefore, [illegible] who have experimented [illegible] hot sun, to ascertain [illegible]

The Palmetto. [illegible] experienced in gardening, especially [illegible] desert this system, [illegible] it we have received in [illegible] of a system to involve the [illegible] some who considered [illegible] in Scotland; or to allege [illegible] grow as freely as common Cabbages as a well-managed garden, or Willows by wet ditches." A man may as well say that Abercrombie, Nisbet, and others of the old school, never did grow Grapes at all. Why, some of the best Grapes ever exhibited before the Horticultural Society were grown in houses heated by common flues. But surely those gardeners would have been glad to substitute hot water pipes for dirty smoke-flues. Every gardener of experience is as well acquainted with the advantages of hot water, as he is with the disadvantages of flues, however well constructed; and any modification of them is but a *poor apology for a perpetuation of the evil.* In the name of gardeners and gardening let us have more satisfactory reasons for abandoning our experience of the last 20 years, of a system which all men of science and practice defend, and which all liberal men, who can be liberal, adopt.—*R. Glendinning.*

Coniferous Plants.—Allow me to observe, with reference to the remarks of "Waldeve," p. 557, that a small work on the Coniferæ suited to the climate of Britain is now in course of preparation, but as it will include all necessary information regarding the recently-introduced Pines, which have not yet been properly tested, it will take a few months to perfect the somewhat contradictory opinions which are abroad respecting them. With regard to the Deodar, Araucaria, P. excelsa, and others, it would be well if planters were to take the trouble to ascertain whether the young trees they purchase have come immediately from under glass, or have been growing under the open firmament. Plants which have been forced into unnatural luxuriance in glass-houses, and are immediately removed to cold and exposed situations, must of course suffer greatly from the change, while the same species reared in the open air will succeed perfectly well.—*J. Gregor, Norwich.*

Societies.

HORTICULTURAL SOCIETY.

Sept 3.—Colonel Fielding in the chair. M. C. B. Cave and W. Stirling, Esqs., were elected Fellows. Of Orchidaceæ there was a considerable number, but among them there was nothing rare or remarkable. Mr. Don, gr. to F. G. Cox, Esq., sent small but good specimens of Cymbidium giganteum, Zygopetalum maxillare, Brassia Cloweslana, Stanhopea venusta, and another species, apparently Wardii, having a fine spike of bloom, together with the variety of Miltonia candida called flavescens, Zygopetalum cochleare, and a good Cattleya Harrisoniæ. From the same collection was also Calanthe variabilis, a small Sarcanthus teretifolius, Eucomis punctata, and a plant of Werrea tricolor, together with the downy variety of Justicia carnea, and an Achimenes pedunculata in good condition, for which a certificate was awarded.—From Messrs. Rollisson's, of Tooting, were plants of Stanhopea venusta, guttata, and a variety of insignis called atrorubens, producing pretty dark-brown spotted blossoms, together with specimens of Oncidium sanguineum, Cymbidium lancifolium, Miltonia Cloweslana, and a variety of the same, named nebulosa.—Mr. Redding, gr. to Mrs. Marryat, sent a fine Cattleya crispa, having five spikes bearing 21 blooms, but almost out of flower; a plant of Eulophia macrostachya, and a specimen of the old Guzmannia tricolor, a dry stove plant, seldom seen in bloom, for which a certificate was awarded.—A cut spike of Stanhopea graveolens, a fine noble looking flower, but emitting an odour by no means pleasant, was contributed by Mr. Errington, gr. to Sir P. G. Egerton, Bart.—Of Fuchsias two seedlings were produced, one from Messrs. Lane, of Great Berkhampstead; another, called Unique, from Mr. Mallyon, gr. to T. Brandon, Esq. The colour of the flowers was somewhat in the way of Chandlerii, from which the latter was raised.—Messrs. Henderson, of Pine-apple-place, sent a plant of Acropera Loddigesii, finely in bloom; Eriosternon scabrum, the small white flowering Erica peritata or purialis, Begonia Martiana, with flesh-coloured blossoms, and a good specimen of Echites splendens, having one flower in good condition, which served to show what a beautiful thing it is. It was introduced a year or two ago by Messrs. Veitch and Son, of Exeter, and is one of the finest climbing plants we have obtained for years. It not only produces fine trusses of bloom for a length of time, but each flower is said to continue in perfect bloom, for seven or eight days, and sometimes even longer.—Mr. Cordon, gr. to T. Hopkins, Esq., received a Banksian Medal for a magnificent plant of Lælia lanifolium album, having eight stems, each bearing from eight to ten expanded blooms, and showing what it is possible for good management to do with one of the finest plants in cultivation for adorning the conservatory at this season.—From Mr. Glendinning, of Chiswick Nursery, was Clerodendron fallax, in [illegible] condition.—Mr. W. P. Ayres, gr. to J. Cook, Esq., received a certificate for a collection of cut blooms of Pelargoniums, comprising some of the best varieties in cultivation.—Of Fruit [illegible] sound, and weighing 3 lbs. The diameter of pips in height was 12. This [illegible] largest which were produced before the Society, and excepting one lately sent from the same garden, it is unfortunately weighed 15½ lbs., it is probably the largest ever grown in England. Independently of its size it was beautiful in form, and is a remarkable specimen of fine cultural skill; there was no disproportion between the crown and the fruit. It was stated to have been raised by a plan constructed by Mr. Mills for growing Cucumbers in. The large silver medal was awarded for it. Mr. Mills also sent a fine specimen of his Champion Cucumber, measuring 21 inches long. Other Pines present, although [illegible] were passed by this time were by no means unworthy of notice.—Mr. Henderson, gr. to Sir G. Buxton, received a Banksian Medal for a handsome Globe Pine, weighing 6 lbs. 13 oz. and measuring 9 inches high and 17 inches round. The number of pips was 9.—And Mr. Fish, gr. to H. H. Oddie, Esq., sent 3 Pines, one a seedling weighing 3 lbs. 11 oz., the other two Providences, the heaviest of which weighed 3 lbs. 7 oz., and measured 8 inches high and 19 inches round. The number of pips was 9. It was a fair specimen of good cultivation; a certificate was awarded for it. Mr. Fish also sent a Valencia white-fleshed Melon, weighing 5 lbs. 4 oz.—From Mr. Murray, gr. to the Marquess of Bute, were 3 Globe Pines, the heaviest of which weighed 6 lbs., and measured 7½ inches high and 16½ inches round. The number of pips was 6.—And, finally, from Mr. Saunders, gr. to C. Hoare, Esq., was a seedling Pine, weighing 6 lbs. 14 oz. It was a well-formed fruit, but was not in such good condition as could have been wished, being ripe on the under part and not at the top.—Mr. Parsons, gr. to A. George, Esq., received a Banksian medal for five fine bunches of Muscat of Alexandria Grapes, and a certificate was awarded to Mr. Jones, gr. to Sir M. Dixey, for good specimens of Grosse Mignonne Peaches. Excellent specimens of Peaches and Nectarines also came from the garden of the Rev. J. Cook, of Newton-hall, Northumberland. They consisted of Red Magdalen and Violet Hâtive Peaches, and Elruge Nectarines, and were remarkable for their size and fine colour. They were stated to have been grown on the open wall, at an elevation of 500 feet above the level of the sea, and exposed to the whole of the blasts of the German ocean. Unfortunately, however, they arrived after the list of awards was made up and in consequence of this no Prize was assigned them.—From Mr. Murray, gr. to the Hon. R. H. Clive, were three varieties of Russian Apples, named Yellow Transparent, Long-striped Whrau, and Yellow Whrau. The transparency in the first was, however, wanting, as is generally the case in specimens produced in this country.—S. Pardoe, Esq., sent specimens of a seedling Apple grown by S. Platter, a cottager at Aylsham; being of last year's growth, they were a little shrivelled, but were nevertheless in a state of good preservation. They were stated to have been, until within the last few weeks, quite firm and juicy. They looked like some sort of Russet, and had the useful property of being preserved in good condition over a second season. A certificate was awarded for them.—Among miscellaneous objects was a Ward's case, from C. B. Warner, Esq., containing Ferns; and two arrangements of the leaf, fixed on paper in a triangular form, by Lieut. T. Tilley, R.N. The first arrangement consisted of the Elm leaf in its upward and downward progress, or through all its growing and fading changes, from the young leaf in April to that of the skeleton, or last stage of decay, in the April of the following year, embracing a period of 12 months. The ripe leaf formed the apex of the triangle, or the point where progress ends, and decay begins. The other design was the Poplar leaf in a skeleton state. A few other leaves of different kinds were added, which not only served to show their structure, but proved that vegetable anatomy might become a very interesting pursuit.—From the garden of the Society were plants of Erica Irbyana, Fuchsia serratifolia, Clerodendron fallax, Achimenes coccinea, and Begonia Dregii, together with Oncidium microchilum, and the rare Achimenes discolor, with beautiful crimson bracts or scales, out of which the pretty Violet blossoms grow. From the same collection were also cut specimens of Rhodothamnus cyaneus, a new Mexican shrub, producing fine terminal clusters of deep porcelain-blue flowers. This species, although inferior in beauty to R. fasciculatus, is nevertheless a great acquisition to gardens. It is expected to prove sufficiently hardy for planting out-of-doors during the summer months; it will, however, require some kind of protection in winter. Along with this were likewise Cut Flowers of a new species of Lupine called L. pubescens, sent from Quito by Mr. Hartweg, having very downy leaves; and eleven plants of Fuchsia fasciculata, a garden variety, showing the effects produced on this kind of plant by the use of different sorts of manures. The plants were all taken from the cutting-pan at the same time, and potted into 32-sized pots. The compost consisted of peat and loam in equal proportions. Of the three eleven plants, which made the best, No. 1 received 1 teaspoonful of Harris's liquid manure to half a pint of water; 2, half the quantity of liquid spread on the surface of the soil; and 3 had the same mixed in the soil. These 3 were nearly equal in every respect. Of the next 3, viz. 4, 5, and 6, the two first had each 1 oz. of charcoal, the one on the surface, the other mixed in the soil; 6 received half an ounce of superphosphate of lime mixed in a pint of water. There were also nearly

equal, but more somewhat inferior to the first three. Other three, 7, 8, and 9, one of which received an ounce of cow-dung mixed in the soil, another a quarter of an ounce of phosphate of ammonia mixed in half a pint of water, the third, half an ounce of sugar mixed in the soil, were still inferior to the second three; and Nos. 10, to which one teaspoonful of Mallet's concentrated liquid manure was given to half a pint of water, was the least luxuriant of the whole. Each of these substances was repeated on the 15th of July, and in order to give them a fair chance, the plants were never repotted after they were taken from the cutting-pan. All these plants were larger and better than No. 14, to which nothing was applied, and which the others were contrasted in order to ascertain the comparative merits of the different substances applied.

Garden Memoranda.

W. Joliffe Croup, Esq., Greenwich.—The glass structures here, although in the town, are of a description which one would little expect to find in such a locality. They consist of a conservatory, a Camellia house, a Camellia house, a large stove fifty feet long, twenty feet broad, and the same in height; a pit for Musas, &c. fifty feet long, and an Orchidaceous house of the same size. The collection of plants is large, and includes many rare specimens. *Mr. Clark*, who is gardener there, pointed out in particular, an Acoanthus Abissinus, 5½ inches in diameter, being considerably larger than one lately noticed in a previous Number of the *Chronicle*.—*D. D.*

Burghill, near Dorking, Surrey.—A quarter of an hour's walk from Dorking, on the Guildford Road, through a pleasant neighbourhood, brings the tourist to the delightful residence of *Mr. Barclay*, at Bury-hill. The approach is through the park, with a wooded eminence on the one hand, and a fine open glade on the other; beyond this the eye ranges over a most beautiful prospect, in which Box-hill, with its white chalky surface studded with numberless—here crowded, there scattered—specimens of wild English Box, stands conspicuous. In front of the mansion, a broad lake spreads over a considerable surface, with several weeping Willows hanging gracefully over its indented margins, and near the centre, a small island crowned with a clump of closely planted Pines. The flower garden is beyond the house, not far removed from the border of the lake, and is neatly laid out with beds, gay with Verbenas, Heliotropes, and similar showy summer garden plants. Pleasant walks have been formed to wind up the wooded hill behind the house, and spaces have been cleared at intervals and devoted to Pines. Many of the Mexican and Himalayan Pines of recent introduction have stood the winter without protection, and without sustaining any harm, with the exception of *P. Devoniana*, and are now growing as freely as many of the more hardy kinds, several having made excellent shoots. The hill is covered with an exceedingly sandy soil; indeed in many parts near the summit it is almost entirely sand, and as the situation is likewise airy without being exposed to severe storms, it affords one of the best situations for growing plants that are scarcely sufficiently hardy to stand our climate generally. *Pinus Lindleyana, Tsuga, cocarpa*, Knightia, *pseudo-strobus*, *insignis*, and many of the more rare species appear to succeed well. The grounds contain a considerable number of species, several of which are large and fine specimens. *Abies Douglasii* is above 30 feet high, and produced cones of perfect seeds last year.—*G.*

NOTICES of NEW PLANTS WHICH are EITHER USEFUL OR ORNAMENTAL.

*Habrothamnus** *elegans*. Elegant Habrothamnus (*Green house Shrub.*) Cultivated Pentandria Monogynia.—The beauty of Habrothamnus fascicularis is so striking that attention is strongly drawn to the discovery of other species as likewise; and the Belgians have already superseded an addition, that now presented, which, although not comparable with it in peculiarities, is evidently a graceful and gay looking plant. We received fresh specimens from Mr Van Houtte, Ghent, in January last, and with them a coloured figure by Mr Van Lindens. We understand that the corolla is of a bright carmine. We have not seen this plant in cultivation in this country but it is evidently a soft-wooded species, to be treated in the same manner as *Polygonums*. It differs from *H. fasciculatus* in its small leaves, and less conspicuous flowers, which moreover are smooth, not downy, from the tomentosa in the shortness of the lobes of the corolla, the broadness of the leaves the smoothness of the calyx, and the terminal not axillary flowers; from *H. corymbosus* is not being destitute of hairs.—*Botanical Register*.

Epidendrum radiatum, Ray-flowered Epidendrum (*Stove Epiphyte*) Orchidaceæ Gynandria Monandria. Allied to both *E. ciliare* and *fragrans*, this pretty species is distinctly known by the cleft form and crisp margin of its lip, which moreover is stained nearly in the middle and very delicately streaked with purple. Its petals too are both shorter and broader than in either of those two species. Its habit is precisely theirs; and the three, considering their constant flowering and very neat appearance, deserve a place in all collections. Besides, this species is ornamental by Cinnamon. A plant of this, received from Mexico from Mr. Hartweg flowered in the garden of the Horticultural Society. We also possess specimens gathered by that enterprising traveller at the Hacienda de la Laguna, by Dr. Schiede. It should be potted in turfy heath-mould, mixed with finely broken pot sherds. During the growing season an ample supply of water should be given, and the atmosphere kept moderately humid. In summer when the sun is strong, the house should be slightly shaded, in order to keep the temperature as near 80° to 85° as possible, without admitting much air. For a few weeks in October [illegible] or no water should be given, providing the house can be dried with steam once a day.—*Botanical Register*.

Cohnemorpha nasturtiana. Nasturtium Cohnemorpha. (*Greenhouse Shrub.*) Icosandria Pentandria Monogynia.—This is one of the most striking of the Swan River shrubs, but owing to some difficulty in cultivating it, the specimens that have been produced Mr Knowles are very inferior to the native ones. In the latter the bracts are large, and of the most vivid reddish-orange, thus rendering the plant indescribably gay; the [illegible] appear from July, gay, and [illegible], a short or branch, in allusion to the beauty of the species.

[illegible] stained with [illegible] interspersed by these bracts, are produced [illegible] upon the plant. We entertain no doubt that [illegible] of the plant shall have been more fortunately [illegible] a general favourite. In the meanwhile pots [illegible] in very sweet-scented. A plant of it flowered last spring belonging to Mr. Groom of the Clapham Nursery. It succeeds best when potted in rough peat, well mixed with coal-ashes or silver sand. During the summer months liberal supplies of water should be given, and as much air as possible. In winter it should be treated in the same manner as *Cape Heaths*—never applying fire heat except to keep out frost. It may be propagated by cuttings in the usual manner.—*Botanical Register*.

Andromeda speciosa. Showy Andromeda. (*Greenhouse Shrub.*) Decandria Monogynia.—A very neat shrub, introduced lately by Messrs. Lodiges with whom it flowered for the first time in January last. It was originally discovered in West Florida, at a place called Apalachicola, by the late Mr. Drummond, from whom we have a specimen. We place the plant, with Sir W. Hooker, in Andromeda, for these reasons. In the first place there seems no sufficient ground for separating from Andromeda the genera proposed by the Dons, which, to our apprehension, are neither limited by solid characters, nor so contrived as to form useful divisions. Secondly, the plant before us will not suit any of them exactly; so that M. Decandolle, who admitted the proposed divisions, although he thrust it into Pieris, a name in which he admits there is no common sense, does so with doubt, and questions whether it may not form a new genus of itself. For ourselves we cannot separate it from Andromeda polifolia. One of the most striking characters in this very distinct species is the peculiar darkness of its leaves, which thus are able to set off the snow white flowers to great advantage. They look like pearls on a negro's neck. It is a pity that the plant should not be hardy, but of that we fear there is no probability. It is, however, probably about as hardy as a Fuchsia, and capable of enduring the mildest winters in the open border. It requires peat soil and the same kind of treatment as Andromeda floribunda, like which it may be increased by layering, which should be done when the plant has finished its growth early in the autumn. It only requires the young shoots to be pegged down, and lightly covered with light sandy peat, and afterwards kept moist. The layers require two years before they are fit for removing from the mother plant.—*Botanical Register*.

Miscellaneous.

Sophora Japonica.—The first tree which was introduced into France is still alive, in the Garden of Plants at Paris, in the ancient School of Trees of Tournefort. It is a single plant, produced from a seed sown in 1747 by Bernard de Jussieu, who received some seeds at that time from Japan. Five seeds of it were put under the care of the head gardener, the father of André Thouin, three of them grew, two of which were given away. This plant was called Arbor incognita sinarum until 1779, when it flowered for the first time. This Sophora is now about 72 feet high. The trunk, measured at 3 feet from the ground, is 2 feet 7 inches in circumference, the height below the branches is nearly 11 feet.—*Revue Horticole*.

Guano.—The island from whence the guano is taken, is about three miles from the shore, on the south west coast of Africa. It is a barren rock, about a mile in circumference, has no soil, nor the least sign of vegetation. The guano lies to the depth of about 20 feet, and without any variation in quality. The continent is very sandy, and in high winds (hurricanes, for instance), will cover a ship's deck nearly 100 miles from the land. The birds on the island are a kind of penguin, and cannot fly to any distance, if at all, their wings being a kind of fin. It is believed that the captain of the vessel who brought the guano was the first human being who set foot on the island, which is very difficult to approach, there being no harbour, and a heavy surf. On walking on it, he could scarcely set his foot without treading on the birds, and they took no notice whatever of him, except perking at his feet, he being barefoot, and on a gun being fired, they merely fluttered a good deal and made much noise. There is no fresh water, it is believed, for some hundreds of miles along the coast, and no rain. The importer, Mr Rae, informs me, in a letter with which he has just favoured me, that his son is the discoverer of the guano isle or islets, for it would appear that there are several of them so remarkably situated. That he was led to go in search of them in the beginning of last year, from remembering having, when a boy at school, looked into the sea-journal of an American whaler, in which mention was made of such spots. And that his first attempt was unsuccessful, and nearly proved fatal to himself and all concerned—he and his boat's crew, in exploring the islets, having almost perished from want of water, before they could rejoin their little "surveying vessel," and then (she, too, being in want of water), having had to sail 1500 miles before they could obtain a fresh supply.—*Dr. Davy, in the Edinburgh New Philosophical Journal*.

The Kestrel, or Windhover.—Of course the whole of the hawk tribe fall under the ban of the keeper. The species mentioned above is that which chiefly prevails in this locality, and whenever the gun can reach him, he is a certain victim. In addition, the nest is eagerly sought for, the young taken, and too frequently with a piece of wood chained to the foot, may be seen in misery hopping, as well as they can, to snare smaller birds from the produce of the garden. The utility this bird confers by the number of mice he destroys, is, of course, never taken into consideration; he is "vermin," as the keeper phrases it, and that is enough. His utility to the agriculturist, from his mice-destroying propensities, has been well described by *Mr. Waterton*. He is a feeder, also, on the cockchafer, but all is of no avail, death awaits him whenever he comes within range. Those who have professional his beautiful action, when hovering over a field in search of his prey, cannot but deeply regret a course which, if pursued in, will ever long deprive them of this pleasure, at least in the neighbourhood of large game preserves. "Would but our country gentlemen," says the same entertaining writer, "put a stop to the indiscriminate slaughter of birds by their ruthless game-keepers, we should not have to visit Holland in order to see the [illegible] habits of the stork, nor roam through Germany to enjoy the soaring of the kite,—a bird once very common in this part of Yorkshire, but now a total stranger to it."

A few evenings past the writer met a cottager, with an undressed hawk and six goldfinches in a basket alive, which he was evidently bringing up for sale. In the other hand were six miserable sparrows fresh from the nest-holes. "Oh, man's ā kill'd all I can get near!" was the rustic's sentence upon remonstrance on his cruelty.—*J. M.*

The Magpie.—This singularly beautiful bird is, unhappily, doubtless keeper's doomed list. But for its habits of extreme caution and sagacity, very few would survive the keeper's vengeance. With, perhaps a little truth in its reputation for depredation amongst a few partridges' eggs, and in all probability resorted to in absence of other food, this aberration is more than compensated for from the incredible number of grubs and slugs, lodged under manure in the pastures, which it destroys. In France and Sweden it is *never* molested, and with the Norwegians they are especial favourites, and with a delightful feeling of Christmas, that they should be partakers of the festivities of that season, a sheaf of corn is placed at the end of their houses for their use. How pleasant would it be if our rich farmers would thus distribute some of their grain for these beautiful birds, in imitation of this simple minded peasantry.—*J. M.*

The Thrush.—Turn in our list as we grieve to say, this early harbinger of spring, and, insensible to the benefits derived from the number of snails he destroys, we behold him if he ventures to help himself to a solitary Cherry. During the prevalence of the unusual dry season (June 1844), the thrush was driven for food to the Holly-bush for its berries; and we grieve to report that 60 of this cheerful songster fell a sacrifice to the gun on a Sunday! In the next summer when wasps and other insects have full possession of the garden, this proceeding—the mixture of ignorance and cruelty—will bring its own punishment.—*J. M.*

CALENDAR OF OPERATIONS
for the ensuing Week

I.—HOTHOUSE CONSERVATORIES, &c.

Many useful plants in that section which flowers in winter and early spring in the stoves, may be brought sooner into flower by checking their growth about this time; this is done by diminishing the usual quantity of water, and by keeping the house drier; others of the same sort may be encouraged to grow as late as they will, in order to succeed them. Every pot plant should be looked over once by the at any time when the weather is bad, during this or the next month. It is not enough, however, that the surface of the pots and the surface of the soil are cleaned over—this days for such gardening is done by the hails must also be turned out of the pots, worms looked after, the drainage renewed from time to time, and if the pot is at all covered with green slime, do not use it, but take a dry clean pot of the same size, than add a little fresh soil to the surface, of the same nature as that already in the pot. When a worm escapes from you in the operation of picking them, or when you suspect one to be in the ball, but cannot find it, mark the pot by putting a stick in it, and by turning out the balls occasionally, you will be sure to come at them some time.

Camellias.—From this time to the end of October, there will be a good deal of potting for flowering galetins for this house. Tropæolum tricolorum and others should now be potted to come in in April. Primula sinensis and auriculas.—The last of the [illegible] should be potted; and also the beautiful varieties of Lobelia fulgens, which, if potted about July, should now be in pots; but October is time enough to pot all these, if they are not wanted for to their usual time. By way of experiment, some of all these and others should be kept back as long as possible, in order to have late flowers of them. The spring-flowering Cyclamens are very desirable plants they should now be potted, and the summer ones should all allowed to get dry, in order to be [illegible] of the latter kind of plants of this genus should always be kept growing in pans, as they are apt to be overlooked; and unnoticed till they are [illegible] while the others are in full growth it may happen that they might receive wrong treatment. See Gardeners excellent papers on this family, vol. [illegible] The earliest sorts of Hyacinths, Narcissus, Tulips, &c. should now be making roots freely in the new pots, and they, as the whole host of bulbous plants must be looked over and arranged for potting. There are few in this order that will do for [illegible], but by potting some of them early in September, and their [illegible] in the autumn, their flowering season may be prolonged, and so with Oxalises. Oxalis purpurea and cernua are two that will stand any degree of forcing, and if potted now and kept near the glass in a stove or forcing pit they would be in bloom by the middle of March. The Oxalis cernua has flowers of a fine yellow as those of the Almanda cathartica. Violets may be potted and [illegible] forcing—look to what has been said about them in former volumes.

Pits, Frames &c.—I have often [illegible] said that one cannot enter into the treatment of plants in [illegible] the nurserymen's system with the different soils, but this is an error. For instance, in the nurseries they are now busy housing many of their finest plants, but it is not much to say that no plants which has been out of doors [illegible] the summer in gardens, should be housed till after the first frost of October are over. Of course they must be [illegible] guarded against frost and beating rain, this is [illegible] the time when waterproof transparent [illegible] most useful. There is a new description of pits also [illegible] wanted for this time of the year—may from the middle of [illegible] until Christmas, according to the season. They are [illegible] wholly inapplicable for this season, owing to [illegible]. We want skeleton frames for the purpose that will let in the wind from every point of the compass, that will exclude rains and dews at pleasure. They should be also so contrived that the sides and ends may be shut up quickly, and be close enough to exclude 6° or 10° of frost. There is nothing new in general use that will suit [illegible] for our greenhouse and half-hardy plants as well as a [illegible] or pit at the beginning of winter.—*D. D.*

II.—FLOWER GARDEN AND PLEASURE GROUNDS.

Out-door Department

Few plants make finer beds, or are more to be depended upon in all seasons, whether wet or dry, hot or cold, than the Ice-plant, and some of the varieties of shrubby Cinerarias, *C. viscosissima*, with its flowers of deep orange, though by no means so splendid as it ought to be, is undoubtedly the most beautiful of the class. It is rather difficult to strike by cuttings, unless when brought in a proper state, and that is when the young wood is a little more than half ripe, at which time they strike freely, if planted in a gentle bottom heat. A hybrid variety, raised from this above by a friend of mine, is not less interesting, being equal in colour, and destitute of that clammy mass of foliage from which *C. viscosissima* derives its name

C. leucrantha, with large yellow flowers, and C. l. nitidifolia, with rather paler flowering ears both free-growing and very useful kinds; and C. rugosa, with smooth-surfaced leaves, is not less interesting. These are the best of the old yellow and orange kinds; but there are many Hybrid varieties raised, which make splendid beds, though they are not so much to be depended upon in the blooming sorts. These are Cleopatra striata, Harlequin, Indian Chief, Stewartii, and one or two others. All these flower freely at the present time. The old Persicifolia, grandiflorum and macranthum are both excellent border flowers, and may be increased either by autumn dividing or through the latter are preferable. Of Lobelias, Salvias, and Gentianellas, both very pretty, but are never likely to become general favourites, perhaps is scarcely worth cultivation. Of Phloxes, Dianthus, &c. there is no need to procure at this time, as plenty of these flowers may be obtained in autumn from a few plants judiciously managed and will produce abundance in the spring.

Auriculas.—Those who have not yet potted off the offsets from their plants should not delay doing so much longer, or the beginning of August will arrive before they are established in their pots. Fill the pots with good rich compost, not too heavy, and put a large piece of broken pot over the hole for drainage, and a small piece of turf over that to prevent the soil washing away. Plant the offsets in the centre of the pot. They should afterwards be placed in a shady situation, and watered until they are established.

Pinks and Picotees.—Continue to propagate plants as fast as possible, and if those that are already potted can be hardened against the winter, by having a slight degree of fresh air every day, they will be much better for them.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Polyanthuses.—If offsets are not planted out, let it be done without delay, on a shady border, for plants made as well established before winter. The plants both of these flowers and Auriculas, will require regular watering and attendance during the dry weather. Layering is usually advisable to be taking place in public opinion with respect to these magnificent flowers, and the properties constituting a perfect flower are much better understood. Loam in time is getting in fresh and good varieties, if flowering bulbs are not to be had, procure offsets—they will grow freely, and a dozen from a maiden root will often prove pleasant. We have heard a high character of a feathered Hyacinth, "Lady Middleton." *Carnations*.—Let the rooted layers be put singly in pots, and where the stock is large, it is usual to have two in each; water very sparingly, without touching the foliage or grass, and place them in a close frame for a few days, till they get fresh root. *Ranunculuses*.—Pick out seedlings as they get large enough to pan the. *Dahlias*.—Good occasional waterings with liquid manure will prove highly beneficial. Thin the buds, and tie up regularly; keep a sharp look out for earwigs. Cuttings may be struck in heat.—*J. R. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—All plants requiring their fruit to be properly supplied with liquid manure, and syringing and moistening the pits after sunshine. Presuming that the necessary arrangement of the plants for the winter is by this time complete, it is necessary to pay strict attention to the keeping a regular bottom heat of about 80°, together proper ventilation (most favourable occasions, and gentle syringings on shutting up the houses in clear weather. Be careful to damp during the heat of the day all plants not yet ripened, and in a growing state. This dry weather affords an excellent opportunity for laying up soils for future use and if not done, this very important part of a Pine grower's business should no longer be put off. For further suggestions on this head, see page 578.

Vineries.—Thoroughly damp during hot weather all Grapes that are ripe, to prevent their losing their pulpiness. This is the first time the latter has been noticed in the case of shanking ripe Grapes and some may say "How unnecessary!" or perhaps "How ridiculous!" Nevertheless, I consider it equally important to have fresh plump Grapes through the winter till March, as to have new open in September. April; and when the fruit has had enough of the Vine, and is sufficiently ripened, I feel convinced that it will keep much better, if shanked from the withering effects of a clear sun. Remove the loose rough bark from the pruned Vines and after washing them well with soft water anoint the whole of the Vine with a mixture of soft soap and sulphur, with warm water, in the proportion of ½lb of soap and ½lb of sulphur to 2 quarts of water. Rub it into every crevice with a sponge, going over the Vines twice or thrice.

Peach House.—Continue to wash the foliage of the trees in the same manner, and give all the air possible, by letting the lights well down, and opening the front ventilators and doors. Proceed with the operations recommended before for the early house; and if the top lights have not been removed before, they may now be taken off to keep the house as cool as possible.

Fig-house.—Not yet fit for Gardeners.

Melon-house.—Endeavour to form temperate fine weather to the best account, by giving plenty of air, shutting up early, and keeping the foliage regularly thinned. Cold nights make a little fire-heat necessary.—*G. S.*

V.—HARDY FRUIT AND KITCHEN GARDEN.

Peaches and *Nectarines* should now be looked over every day, and the fruit gathered before it is dead ripe. If placed on shelves in the fruit-room, with soft tissue or silk paper under each fruit, they will keep better than if allowed to hang on the tree. After gathering what fruit was ripe the trees might be sprinkled with fresh water in an afternoon after three fine days, but unless in extreme cases it would not now be advisable to water any more at the roots, as the sooner the growing wood can be stopped and the maturing process completed, or assisted by the autumn rains, which we may expect before long could be thrown off the borders by tiles paddled with clay, or by boarding &c. We should advise fresh borders for winter. If the borders have been allowed to get dry in July and August, and or deluged with rain in the latter end of September and October, unless the Gardener has paid particular attention, a second growth will take place, the consequence of which is barrenness with a superabundance of watery fruit, and a severe winter causes black and brown spotted, shrivelled, cankered, and dead wood in the spring will be the inevitable result. Should Apricot trees have their leaves slightly spotted, with soft wood, instead of ripening at the roots, the leaves might be syringed with sulphur and water.

Kitchen Garden.—Endeavour whilst protecting the last sown put of Beans in case of unusually cold nights frost warded off may chance to supply for a night or two. Where hoops and mats are not applicable, as should have fixed upon stakes, so as to be moved obliquely or horizontally as occasion requires will answer the purpose. Onions should now be got up and dried in the sun, until the tops are thoroughly withered. Then is the best season for gathering them and stringing them, and hanging them against a wall, or such a pole which they will be safe from frost. A Gourd Pole may conveniently be placed out; and the frost can be kept off in a wet day, to prevent them sprouting early next season. *Mushroom spawn*.—Those who grow Mushrooms only at certain seasons cannot do better than procure it from some nurserymen, who generally obtain it from many who obtain it extensively for sale. Where Mushrooms are constantly wanted the gardener can use the spawn more liberally, when he makes a quantity himself. Take heed to all particulars about the materials, horse-droppings and bedding, in a dried state, proportions, with a little road-drift, well mixed together, answer very well. It may be made into bricks with a mould, and put in a shed to dry, or merely spread out on an upward piece under cover about two inches thick, and divided into the size of bricks by cutting with a sharp edging iron. Make two holes in each brick for spawning, and keeping them dry enough for that operation is all that will now be required. *Celery*.—The first crop is beautiful this season, owing to those being the best to set the centre of large beds. Give successive hoeings, a good watering before earthing them up. *Beetings*.—As in former Calendars.—*R. F.*

Fruitful.—For "Fingarth," in last month's Calendar, read this head, line 21 from top, read "Fingarth."

VI.—ARBORICULTURE.

Old Woods.—Where planting is to be done in the ensuing season, the ground should now be trenched and levelled for the purpose.

Coppice.—Attend to grubbing the stumps, cutting the roots of dead and wet weather continuing, prepare them for being hedged. Fill up vacant spaces, as in the Fir, Spruce, Pine, Larch, Tyrannus, holm, and dwarf the oak, if subsequently during the planting season arrives.

Young Plantations.—Preparations for planting, and making good all failures in last season's planting should be completed with all expedition. In mild and open weather, the autumn planting should be preferred; but in all cold, wet, and bleak spring is the best time for the operation.

Hedge rows.—Dead plants of last season's planting should be taken up, and the holes left open sufficiently for filling up with fresh plants as soon as the season arrives.

Nursery Work.—Hoeing, weeding, and training young shoots of the present year's growth, is the principal work to be attended to here at this season.—*W. B.*

VII.—COTTAGERS' GARDENS.

Although there is everywhere an abundant crop of Grapes this season, yet in consequence of the bad weather we had in spring, they will be late in ripening, and will not on that account be well flavoured. The shoots should be kept closely fastened in, so as to receive the full benefit of the wall, not only for the sake of bringing the fruit faster to maturity, but also for thoroughly ripening the wood intended for bearing next year, before winter. It will also be advisable to go over the Vines again pinching off the laterals, and removing all useless growth. Gather and store Apples and Pears as they ripen on dry days too much care cannot be taken to prevent bruises, and be sure also that the kinds are ready for gathering. A good way of ascertaining this is to divide one; when if the seeds are brown they may be gathered. A few Lettuces and Endive planted out now in a favourable situation will be strong good plants by November. A plantation of Cabbages may also now be made; plant them one foot apart as for Coleworts, and in spring every intermediate row may be drawn out for use as Coleworts, and the remainder left to form hearts for Cabbage. Do not omit to attend to growing crops; keep them free from weeds, and in dry weather draw a little earth to them as they advance. All decaying Annuals should be removed from the flower border and let everything about the cottage be as neat as possible.—*J. M. H.*

State of the Weather near London during the week ending Sept. 7, 1844, as observed at the Horticultural Garden (Chiswick).

Aug.	Mornings	Max.	Min.	Max.	Min.	Mean	Wind	Rain

Sat. 14	67.9	45.9	56.9	9	0.9	

The highest temperature during the above period occurred on the 14th 1841, when it was 84 and the lowest on the 10th 1841, when it was 37.

Notices to Correspondents

Balsams.—*O*.—The following are desirable sorts, viz., Double Lilac, Double White Rose White Scarlet Scarlet Black, Red Lake Purple Flake Mottled Purple Mottled Red, Mottled Scarlet and Purple.

Bees.—*F. F*.—If the Bees sent all were furnished with stings, except one. The cause of their death apparently is want of food. Although you state that there is no appearance of any robbery going on, we imagine that if you watch attentively you will find that such is the case. We were shown a hive lately under similar circumstances, the honey of which was nearly all carried off by intruders, and many of the inmates were in consequence in a weak and dying state.

Bugs.—*A Dup*.—Mr Hearne's work on the Vine is under consideration.—*W. R. S*.—There is no small book published exclusively on the subject you mention; but much of the information you want is to be found in "Harriman's Horticultural Calculator."

Heating.—*V*.—If you use back ventilators you cannot employ them in a north or north east wind. We much prefer ventilators in the roof or at the side. Your south aspect is a disadvantage and we would not go to the expense of moving the house. With moveable sashes in the roof, and sliding sashes at the sides you will have all the air you can want. If you adopt the Potmanse system we shall hope to hear the result.—Of this you may be sure, that if you can conveniently make the inside fittings of wardrobe, or some such soft material, it will be far better than wood.—*An Irish Gardener*.—Put one flow and one return table in your kitchen, one flow and one return 4-inch pipe round your house. Have the pipes clear with evaporating pans on them, which you can use or not at pleasure. Leaves may be placed on the pipes, but do not use sawdust, which is a very bad conductor. *R.* — may have the boiler partly inside the house if you like, but be sure that when you are repairing you put on the top of it. If you use oil it should not have a tin pipe to it, but a copper one. You should read what has been said on this subject in former Numbers of this Paper.

Insects.—*R. Abingdon*.—The Frog-hopper, are described in the Index of Titles Cleroderma you will find their economy and best modes of destruction, in the Vol. VII. p. 561.—*R. Sch. R*.—*W. Jones*.—The Caterpillars feeding on the Elm are the larvæ of a Saw-fly, probably Emphytus Grossulariæ figured in Curtis's Brit. Ent. pl. 81. Please to send your address, as he wishes to communicate with you.—*J. B. W*.—The Grub on complaint of are the covering of the Pinetum exclamatio is, whose history will probably be found in this Journal. You will find hand picking the best remedy.—*R. Lawns*.—*J. R*.—To improve your lawn the first thing is to grub up all the weeds and very shovel Grasses; the next to throw down casts of the Crested Dogstail, Meadow Fox, and Hooper's Retour Grasses, with a good supply of white Clover, and the Perennial Rye. When done, it should give it a good dressing of soot, with additions composed of small quantity of guano, and about ½ part of salt per acre. We never give Gishurst compost and similar rubbish.

Manures.—*A Subscriber*.—Your information he thinks for at p. 571 of this year's.—*Beadell*.—Guano is thoroughly soaked with urine as may do for coarse purposes, provided it is not fit for sweet but it is a bad material. You had better burn it and use the ashes.

Mildew.—*A B*.—Drought, in conjunction with the Red Spider, have caused the destruction of your Beech-wood Melons.

Mushroom Spawn.—*W. F*.—We dare say your spawn is good, but that can only be ascertained by trying it. There is some advantage in having it in cakes, as known also instead of bricks; and we think with you that it is a convenience to the buyer.

Names of Fruits.—*A Poor Parishioner*, 1, Noblesse; 2, Royal Charlotte, 3, Grosse Mignonne, 4, Late Admirable. The Nectarine is the Violette Hative.—*E. B*.—Your Plum is the Blue Perdrigon.—*W Veale*.—Your "early pear," between the Green Gage and the Orleans, is not equal in quality to the Washington Plum, which in other respects it very much resembles. Its real specific name is——*G. L*.—No. 1, Coe's Golden Drop, and appears to be the Red Pearmain; and 2 is, probably the Pomme Royale.—*A M*.—Fulham, No 2, Williams's Bon Chrétien; 3, Summer Boncrétien; 4, Passe Colmar.

Names of Plants.—*A Reader*.—Bignonia grandiflora. The little bulbs on Achimenes pedunculata will make fine young plants.—*Superstition*.—Such spots on roses, though not very uncommon.—*J. W*.—Quamoclit is the Mexican name of the plant.—*A Reader*.—Viburnum tomentosum, from the Himalayan mountains.—*Subscriber*.—Your specimens received; we do not know.—*W. P. A*.—1 Dianthus Caryophyllus; 2 Saponaria officinalis; 3 Dianthus plumarius; 4 Campanula Trachelium.—*A Constant Reader*.—Orchis latifolia.—*Inquirer*.—Not enough to identify.—*T. S*.—Bryum cuspidatum, by any means common in some parts of the country.—*A Devonian*.—Ipomæa, now called Convolvulus purpureus.—*G. B. R*.—Variety of Pelargonium.—*Campanulatum*.—*A. T*.—Apparently Spondias Cytherea, which never attains a large size. A greenhouse would suit your purpose better.—*W. T. Folsome*.—Figured in Bot. Mag. as Fungi, t. 1164, under the name of Lycoperdon cerinum.

Oxalis.—*Q*.—These thrive well in almost any light sandy soil, such as peat or leaf mould. After flowering, they naturally lose their foliage, which they should be kept dry to last weeks. As soon as they show symptoms of growing, they should be repotted, and placed in a greenhouse; but let water be sparingly given until they begin to show flower. They may readily be multiplied from seed, or by dividing the bulbs which they generally form above their roots.

Pansies.—*W. R. S*.—These will be quite strong enough to stand the winter if planted out when the weather becomes moist, towards the end of September or the beginning of October, but they must not be planted either in very rich soil or in a damp situation.

Peaches.—*Alligon*.—Noblesse and Royal Charlotte are the two you should take. We conceive it is quite practicable to dress Peaches in boxes.

Pears.—*E. F*.—The Vicar of Frome and Marie Charlotte, are recommended for the earliest sorts. In succession, the Alvergat will fulfil most of the desirable properties you enumerate.

Wasps.—*J. R*.—Your mode of destroying these insects is the old and inconvenient plan. If you will try turpentine you will never again have recourse to so clumsy an expedient as gunpowder.

Whitney's Composition.—We have received from Mr Whitney some Black Hamburgh Grapes grown under his caloo sashes, and we can state that they are perfectly well coloured and good berries. Mr. W. states that the average weight of the berries was 140 grains, and that the foliage is "particularly beautiful."

Miscellaneous.—*C. B*.—You will find many plans of Hothouses in our columns. We do not give estimates, that is the business of a builder.—*W. S*.—Nos. 10, 22, and 42, may be had at the Office; and 8 is out of print.—*A Scottish Botanist*.—We know of no precise distinctions between such genera, species, and varieties, are founded, nor is there in any publication a brief and clear enunciation of their differences. The common definition is this:—A species is a collection of individuals which were originally created distinct from all others, a genus is an assemblage of species more like each other than anything else; in order to a similar collection of genera we have a consistent system of species.—*Bella*.—Wistaria consequana is the plant more generally called Chinese sinensis, with which you are doubtless well acquainted. We know nothing of W. speciosa. W. frutescens is like the first, but very inferior in every respect, and not worth growing except as a variety.—*R. G*.—We saw the Pomegranate, and wrote to Mr Grimstone about it, to inquire if it was true. As we have instructed him reply, we presume the story to be a mere exaggeration.—*A. R. Harris*.—It is true that deformed Cucumbers are frequently preferred for seed. The reasons are, that they are less fit for table, and bloodier more seed. That accidental deformity does not impair the quality of the seed.—*J. N. G*. will find a select list of Conservatory plants and climbers given at pp. 580 and 581 of the present year's.—*A Quiet Observer*.—The examination of the Flower and the report of the Committee have appeared in the Horticultural Register. You had better apply to Mr. Lodge.—*South Lancashire*.—Both Plocrest and Cuthbertson the Derwent brook, the Dianthus Carnation Flora, which you obtained first we do not know.—*A Y*.—We find a list of Roses given at p. 779 of last year's.—*D. D*.—Your word Vegetable Marrow is Cougourda in Martin of the Provence.

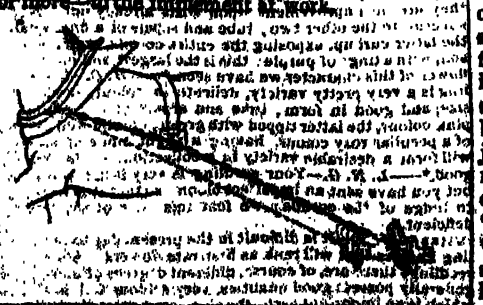
THE HARDY FLOWERS.

Fuchsias.—*W. L*.—Both your seedlings are bright and well-coloured flowers, but wanting the violet colour in the corolla, these do not materially differ from many others, nor can they be distinguished from many others; we only name.—*Y. L*.—Miss Gould's are large flowers, but the tube and sepals in both are coarse, and they are no improvement upon sorts already out. No 3 is superior to the other two in the tube and sepals of a finer quality; the latter curl up exposing the entire corolla, which is crimson, with a tinge of purple; this is the largest and most showy flower of this character we have seen.—*H. C*.—Your seedling is a very pretty variety, delicate in colour, moderate in size, and good in form; tube and sepals of a very delicate pink colour, the latter tipped with green; corolla well expanded, of a peculiar rosy colour having a slight tinge of violet; it will form a desirable variety in a collection, if the habit be good.—*L. N. G*.—Your seedling is very large and showy, but you have sent an imperfect bloom, so that it is impossible to judge of the corolla; we fear this part of the flower is deficient.

Hawthorns.—*W. T*.—It is difficult in the present day to raise seedling Pæonies that will rank as first-rate flowers. Among your seedlings there are, of course, different degrees of merit; they generally possess good qualities, very seldom fail in the eye, which is an important part; the side petals must move the eye, with the colour and form good also; but generally they want the size and substance of the flowers we see in the habit of sorts at nurserymen's. The inferior sorts sent are Nos 1, 3, 6, 7, 9, 8, 10, 11, 12, 14, 15, 16, 18, and 21; these possessing good properties, but rather under the standard size, are 2, 4, 5, 13, 17, 22, 23, 24, 27, 28, and 19, 20, 26, are fine in size and substance."

SEED WHEAT. [illegible] WHITFIELD FARM, [illegible] during the last [illegible] —JOHN MORROW, Whitfield.

The Agricultural Gazette.



[illegible]

Before proceeding further with our report on Agricultural Mechanics, we shall place before our readers the following remarks by a correspondent on the subject of our last week's Article, THE DRAUGHT OF FARM IMPLEMENTS.

"If I understand your plan aright, you intend to describe the construction of each of the machines you notice—1st, in reference to its efficiency; and 2dly, as affecting the power required to work it. The first of these subjects has but few general bearings. To be sure, in entering upon the consideration of implements of cultivation, you might have prefaced your observations by an inquiry into that condition of soil to be produced by their combined action which is most suited as a seed-bed, or as a vehicle for conveying nourishment to the roots of full-grown plants. This, however, you have greatly supplied, but the subject of draughts in our agricultural farm implements generally, and it is one of great interest and importance. Your descriptions and illustrations of the means we have of measuring it are satisfactory and well placed; but, with the exception of a few sentences on the want of constancy in the density of soils as producing an extreme variability in the draught of all implements of cultivation, your remarks on the subject have not that general bearing which they might possess. In order, therefore, that your introduction to the subject of Agricultural Mechanics may not be characterised by any glaring incompleteness, will you allow me to make a few further remarks on the draught of farm implements?

"I do not allude to the mere *quantity* of draught—the sources of power employed—the economy, in certain cases, of using steam-power—the comparative expense of horse-labour, and that of oxen—a subject, by the way, highly worthy of discussion in your columns; nor do I allude to the variety of the methods adopted in arranging the cattle before the implements they are to draw—as in *tandem*, *randem*, *unicorn*, teams, and teams of two or three horses abreast. The merits of these various modes of arrangement must be determined almost solely by a consideration of the facilities they severally afford for enabling the horses advantageously to apply their strength; and a slight consideration, though I do not intend entering upon it now, will, I think, point out the superiority to all others of the mode of harnessing cattle abreast. There are farmers, however, who defend their practice in this particular, upon the assumed safety it affords against injury to the ground by trampling. Reasoning of this kind must be fallacious, because, if two teams be of equal number for every furrow that is opened, the same number of horses must walk across the field, whatever be the mode in which they may be harnessed to the plough. The only possible distinction in this respect between two 2-horse teams, the one abreast and the other tandem, is that while the trampling of the latter is all in the furrow, and tends to the production of a hard pan or bed a furrow's depth from the surface, that of the other—as I think, less liable to be injurious—is partly in the furrow and partly on the unturned land.

"In the remarks, however, which I have asked permission to make, I allude more particularly to the mode of harnessing cattle—be they horses or oxen, one or more—to the implement at work.

"In the above figure it will be seen that the draught-chain of the plough, instead of proceeding in a straight line from its attachment at the frames to the plough-beam, makes an angle at the back-band with those points.

"The back-band is in fact so short that it carries the chain-lever from the point of its attachment to the collar; and thus, as I may incidentally mention, it constitutes a simple mode by which the ploughman can alter the line of draught. If the plough tend to smack into or out of the ground, or more readily to run [illegible] he can [illegible] by merely shifting the chain-lever in the [illegible] fair at the desired depth; and the back-band, by being [illegible] affords the means of altering in either way the direction of the line in which the effort of the animal is to be exerted.

"But the chief merit of this simple arrangement is, that it takes a portion of the draught from the shoulders, on which all of it formerly fell, and brings the muscles of the back into play. There are several advantages derived from the use of this back-band; the bringing of the back of the animal into work increases its capability as effectually as if a new source of power were called into action, and not only so, but the arrangement by which both shoulder and back are made to pull, tends to compress and force together the acting muscles of those several parts, and thus to produce that firmness and rigidity of its parts, which must give the horse additional confidence in its own powers. The arrangement of draught harness upon draught animals is thus a matter of considerable importance; and as it is equally so, whatever be the implements at work, I thought these remarks upon it would be properly in place at the commencement of your Articles on the Machines of Agriculture.

"It is a very general and probably accurate idea, that power, to be advantageously applied, should be near the work to be done; though how to explain satisfactorily the advantage which appears to arise from this practice, I do not know. The only two apparently influential causes in producing this effect, viz., the additional weight of draught chain to be carried, and the indirect application of the animal's power owing to the slight additional bending of the line of draught consequent upon lengthening it, appear insufficient to account for it. Be this, however, as it may, the advantages of the mode of harnessing that I have been describing, are such as to justify the slight increase which it occasions (see woodcut) in the distance of the horse from the implement it is drawing.

"It is no small advantage of the system of harnessing draught-cattle abreast, that it affords an opportunity for the adoption of this simple mean of so materially assisting the effort of each of the animals in the team, taking it from the few muscles which are brought into play by resistance to a pressure on the shoulder only, and distributing it more evenly amongst these and others."

To this we have only to add, in proof of the importance of a right way of harnessing cattle, that, though in working most Scotch threshing-machines an arrangement is made by which the effort of no horse can exceed a pull of 10 or 12 stones in weight, while in ordinary plough-work a pull of 15 and 20 stones is often exerted, yet the work at the threshing-machine is universally considered the more severe upon the animals: the reason, so far as we can see, being that, in the former case the resistance to be overcome being all above them, no such advantage as has been here stated to arise from the use of the back-band can be experienced.

A THIRD edition has been lately published of the excellent pamphlet by Mr. H. Davis, on THE WASTE OF CORN IN THICK SOWING; and we take the opportunity of noticing it, in order at the same time to publish the results of an experiment on the proper width of drilling Wheat, to which we have before alluded (p. 413). A 10-acre field was divided into various lots of nearly one width, and sown with Wheat in November last, the drills being at intervals of 7, 9, 12, 15, and 18 inches, respectively. The soil is mineral uniform as regards the width of the field, but it varies in its character longitudinally. It is a loamy [illegible] upon the [illegible] sandstone formation, and, about two-thirds of the way down the field, a bench of rock [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] of springs occur, and formerly the land there used to "poach badly in wet weather;" but, by the [illegible] [illegible] [illegible] [illegible] springs, that the operations of draining and levelling having now been completed, the soil is in a friable and [illegible] [illegible] [illegible] tion of the field, therefore, as well as that where the soil is shallow, has been excluded from the following calculations. In the month of July two lines, parallel to one another, and 5 chains apart, were laid out across the field, including between them the greater portion of the upper part of it, the soil of which, as far as the farmer can judge, is of a perfectly uniform character. The plots, being about one chain wide, thus consisted of about half an acre each. To this, however, an exception must be made; the land on the north side of the field having been pared and burnt [illegible] [illegible] [illegible] rest of it in the [illegible] experienced, was excluded from [illegible]. In determining the number of [illegible] [illegible] [illegible] that side, though of the same [illegible] as the others, was only [illegible] [illegible] [illegible] thus, on walking across the field from south to north, were experimental plots [illegible] [illegible] [illegible] rows 9 inches apart, the seeding being at the rate of 6 pecks per acre; [illegible] [illegible] were 18 inches apart, and the seeding three pecks an acre; on No. 3 the rows were 6 inches apart, and the seeding 9 pecks an acre; on No. 4 the rows were 12 inches apart, and the seeding 4½ pecks an acre; on No. 5 the rows were 15 inches apart, and the seeding 3½ pecks per Acre; on No. 6 [illegible] [illegible] inches apart, and the seeding 6 pecks an acre. The land last year [illegible] [illegible] [illegible] fair and uniform crop.

We are thus careful in detailing the particulars of this experiment, in order to assure ourselves from what experimenters on any point in Agriculture are peculiarly subject to a liability to mislead others, and still further to insure an accurate appreciation of this experiment, it must be stated that the weather has, during this season, been one of almost unparalleled drought—one, indeed, in which thick sowing was advisable, if ever it has been so. We must say generally of this experiment, that the extent, the character of the soil, and the general attention which has been paid to secure its accuracy, has all along given us confidence in its results, whatever they might be—a confidence which, if nothing existed to impair it before, could, of course, be rendered now that the results are known. With the exception of one point [illegible] harvest, viz., the general superiority of the crop on the north side of the field over that upon the same width on the south side of it, we know of nothing to hinder us from believing that on siliceous sandy soils in good condition, with such a season as the present has been, the following results of this experiment would be generally experienced:

No. of lots.	Width of rows.	Quantity per acre.	Number per acre.*
	inches.	Bushels.	Bushels.
1	9	[illegible]	[illegible]
2	12	[illegible]	[illegible]
3	6	[illegible]	[illegible]
4	15	[illegible]	[illegible]
5	18	[illegible]	[illegible]
6	9	[illegible]	[illegible]
7	9	[illegible]	[illegible]

* These were ascertained from the yield carefully weighed and measured, and from the size of the different pieces exactly measured. Excepting No. 1, the plots differed but little in size, and averaged half an acre each.

No mention is made of failing Corn, for the simple reason that there was none. The grain was all well berried and plump, [illegible] [illegible] more than 64lbs. per bushel. There was a few tares, as they are provincially termed (*), [illegible] separated from their husk, amounting, perhaps, to one bushel in sixty; these were not separated before weighing, but on afterwards [illegible] them by sieve, there appeared to be more where the grain was sown thickly than in the other plots, probably owing to the produce being finer there, and the husk thus more readily breaking off along with the grain in the threshing.

What inferences are to be drawn from this experiment? The appearance of superfertility in the crops on the north side of the field has been fully borne out by the results, and in point of fact there is a much greater difference between two of the plots (Nos. 1 and 3), in which Wheat was sown in equal thickness, than there is between two plots (Nos. 2 and 3) in which the Wheat was sown in thicknesses differing most from one another. However, no great results can arise from comparing adjacent plots, and let any advocate of thick sowing compare the produce of the 18-inches drilled Wheat with that of the 9-inch Wheat on the one side, and that of the 6-inch Wheat on the other; and say if, considering the drought of the season, he is not surprised at the slightness of the difference between them—a difference so slight that it is almost compensated by the saving in the seed.

May we presume that the superior fertility of the north side of the field is the result of a *uniformly* increasing superiority of soil as we walk across it from south to north? If so, then subtracting the 0 bushels and 10lbs. from No. 7—the amount in which it exceeds the produce of plot No. 1 sown equally thickly—6 bushels and 10lbs. from No. 6, 6 bushels and 32lbs from No. 5, and so on uniformly

* A provincial term, descriptive of a 3-horse team, 2 being abreast, and 1 in front of them.

decreasing to 0 as the amount to be subtracted from No. 1, we obtain the following results:—

Number of Lots.	Width of rows.	Grain per acre.
	Inches.	bushels. lbs.
1	9	76 56
2	12	64 14
3	6	84 47
4	12	31 56
5	15	25 09
6	9	35 46
7	9	80 60

If this be a justifiable step in estimating the results of this experiment—and from the manner in which it assimilates the produce of the plots which were sown equally thickly we may presume that it is—then, though the weather has been such as most remarkably to favour thick-sown crops of all kinds, yet it has not been sufficiently dry and scorching to hinder the plants of plot No. 2 from as nearly as possible equalling in produce those of plot No. 3, though not, by two-thirds, so thickly planted in the ground.

The subject of the quantity of seed per acre from which the maximum benefit is derivable, is one of great interest to the farmer; the seed-Wheat alone of many farms equals a quarter of their rent in value, it is a subject which we hope to see taken up by many of our practical readers. We have this week received an interesting account of experiments performed last year near Bath, which we shall publish in our next Number, and we hope that the experience of others will be placed at our disposal, in order that from the comparison of numerous results a trustworthy conclusion may be arrived at.

We conclude by quoting from Mr. Davis's pamphlet the following defence of the practice of thin-sowing Wheat. His practice on the large scale is to sow but 3 pecks per acre.

"The yield of an average ear of thick-sown Wheat is about 30 grains (I say thick-sown, for thin-sown yields very much more), and therefore, as the ordinary return off every acre is at most about 30 bushels, it follows that this quantity, no matter how much has been sown, can at most have come from the growth of the ears from one bushel of seed (and that, too, is allowing only one ear to grow from each grain, and 30 grains from an ear). This being the fact, of what use can more seed be, or rather let me ask, must it not prove injurious; what becomes of the remaining six or eight pecks of seed which are commonly sown; and how is the excess of plants, thereby produced, to be gotten rid of without injury to the remainder? In allowing one ear only to grow from a grain, and each ear to contain only 30 grains, I am very far from taking what should be the produce; for a single grain, having room, will throw up 10 or 12 ears, and these ears will each contain from 60 to 80 grains, so that in fact the yield, were room given to each seed to tiller out, instead of 30 for one, which is all a bushel of seed allows, would be many hundred-fold; and hence any provision for the loss of seed from vermin or birds is unnecessary, for supposing half, or much more of my small allowance, to be taken away or destroyed, the deficiency of plant will be immediately met by the tillering and the larger size of the ear, which takes place wherever room admits of the increase. Among the many proofs I have had of the advantage from thin sowing, the following is a striking and, among my people, well-known fact. In the autumn of 1840, I had to sow with Wheat a field of eight acres, and to do this seven bushels of seed were given out, but owing to an error of the drill-man in setting the drill, when he had sown half of the ground, he found he had not put on half of the seed; then that I might not discover, by the overplus, his mistake, he so altered the drill as to sow the rest on the remainder of the field, and in this way our half had little more than two pecks to the acre, whilst the rest had nearly four pecks. I did not know what had been done, and was therefore surprised and frightened in the winter by finding part of the field very thin, and, had not the rest looked very much better, should have ploughed it up; but in spring and summer, a decided superiority in the growth of the thinner portion became perceptible, and at harvest this part proved the best, and I should never have known of the error in the sowing but for this result having induced the drill man to point it out to me."

It is only by experiment and observation, whether of a designed or accidental, but especially of the former character, that truth in the matter can be ascertained.

ON FLAX-SEED AS FOOD.

(Continued from page 594.)

EVERY farmer is aware of the value of oil-cake as food for cattle, which is merely the refuse matter of Flax-seed after the expression of the oil. Indeed, such a nutritious article of food has this been found, and so much superior for the production of fat to any article of farm produce, that animals fed on it have usually been disqualified from competition at the national and local farming societies' Shows. But much valued as it has hitherto been, there is good reason to believe that it would have been still much more valuable were it free from adulteration. Flax-seed, like every other article of farm produce, is very various in quality; so that strict uniformity in the quality of the oil-cake produced from it, is not to be expected. The variation will, however, be greater in the quantity and quality of the oil than in that of the cake; so that, were no means employed for adulteration, the quality of the latter would be found more uniform than it usually is; nevertheless, in nine-tenths of the oil-cake exhibited in the British markets, the refuse of other seeds, frequently those of weeds, will be found to constitute a large if not the greater portion of it. Oil-cake, however, still continues to maintain its ground among cattle-feeders, notwithstanding the extent to which it is adulterated by the admixture of foreign substances—a fact which speaks volumes in its favour as an article of food. It is, of course, impossible to state to what extent its value is depreciated by such admixtures; but the loss, in a national point of view, from this source alone, must be very considerable, when so much as from fifty to one hundred tons of oil-cake are annually consumed, in some cases, by individual farmers.*

It does not appear that we are in possession of any correct proximate analysis of the seed of the Flax-plant, which is evidently of more importance in the estimation of its feeding properties than an ultimate analysis, of which latter several have been published. In the somewhat imperfect proximate analysis quoted by Professor Johnston in his Lectures, the principal ingredients are stated to be as under—in 100 parts:—

Oil	11.3
Husk, &c.	44.4
Sugar	10.8
Gum	7.1
Soluble albumen (casein)	15.1
Woody fibre, starch, wax, and resin, &c.	11.3

This analysis, continues the learned Professor, shows that the seed of Flax contains considerable proportions of gum and sugar, and a large quantity of a substance here called soluble albumen, of which nitrogen is a constituent part, but which differs in its properties from the gluten and albumen of the seeds of Corn-bearing plants, and has much resemblance to the curd of milk. Besides their fattening properties, therefore, which Flax and other oil-producing seeds owe in a great measure to the oil they contain—this peculiar albuminous matter ought to render them very nourishing also; capable of promoting the growth of the growing, and of sustaining the strength of the matured animal.†

It is certain that the loss sustained by the expression of the oil in Flax-seed, as food for the domestic animals, is much greater than the money value of the oil itself; and that, therefore, besides guarding against imposition, *in the form of adulteration*, it would be more economical, on the part of the feeder, to use the Flax-seed itself, in preference to the oil-cake. Nor is the management to be adopted in the latter case difficult to be carried into effect. The seed is merely reduced to meal and boiled, when a jelly is formed, abounding in mucilage and other nutritious matters, which may be used in combination with almost every other kind of food. For every pound of meal, two gallons of water may be employed, to which may be added, after the mixture has boiled a few minutes, a proportion of bruised Oats, Barley, refuse Wheat, or other similar matters, with a quantity of cut Hay or Straw, sufficient to impart a degree of consistence. After simmering over a slow fire for a few minutes, this will absorb the mucilage, and the mixture will be ready for the animals when cold enough for use. A little experience will show in what proportions the various ingredients which may be used can be most economically employed. Potatoes, or other roots, cut Hay or Straw, Clover—in fact almost every article of farm produce—may be used in conjunction with this mucilage, as food for every one of the domestic animals.

But it is not necessary to dwell at great length on this part of the subject, as no difficulty will be experienced in the preparation of the food. I shall, therefore, proceed to describe the management at Honkesley Hall, alluded to in my last paper on the subject, which I am enabled to do through the obliging attention of the Rev. Mr. Blair Warren, whose course of management in reality seems to be well worthy of imitation. The system which he carries so well into operation is, however, that of Mr. Warnes, of Norfolk, whose exertions in this department of farm management have been noticed in my last paper on this subject.

The preparation of the compound may take place in a common boiler, but where a considerable number of animals are to be fed, the process will be much more economically and conveniently performed by steam; and the expense of the erection of an apparatus for this purpose will soon be repaid by the saving of labour and fuel thereby effected. By means of pipes steam is conveyed from the boiler in which it is generated to one or more vessels placed convenient to it; and the water in these vessels may be boiled altogether through the instrumentality of the steam thus introduced; or a portion of it may be drawn off from the boiler itself, by means of a stop-cock—in which latter case the preparation of the food will be materially hastened. While the water in these vessels is kept boiling in this manner by the steam conveyed to them, the required quantity of Flax and meal is to be gradually added, the mixture during the time being stirred about. Flax-seed, in its whole state, is well known to require lengthened boiling before it can sufficiently impart its mucilaginous properties to the mixture; but when ground into meal it does so rapidly; in fact it is only in this state that its nutritious properties can be properly developed. After the Flax-seed has been added, and the whole boiled a few minutes, the farinaceous matters to be afterwards added should be in readiness, observing that the grain or pulse employed should be bruised, and the Hay or Straw cut into chaff. The quantity and proportions of each of these matters will, as has been already observed, depend on the peculiar circumstances of the farm, and the intention of the feeder. The refuse grain, which, could not in other cases be perhaps profitably appropriated, is here economically applied. But the presence of other farinaceous matters, though desirable, is not absolutely essential in using Flax-seed jelly. It may be advantageously employed in conjunction merely with cut Hay or Straw, or any description of green feeding, as Clover and Grass, Vetches, Lucerne, &c., after being cut by the machine, to prevent waste.

The system of feeding on compound of Flax-seed, &c., may be carried on in conjunction with pasturage or any other plan of house-feeding. During the summer months, when the cattle and sheep are on their pastures, they may be supplied with a portion of the Flax-seed mixture once or twice a day; and one of the beneficial effects of such a course of feeding will be, to make the animals relish and eagerly consume the most inferior descriptions of herbage, on which they would otherwise starve. The supply of Grass may also by these means be greatly economised, especially in the case of sheep feeding, as they may be confined by hurdles to a given extent of the Grass until they have eaten it down, and this will not only economise the Grass, by causing it to be all eaten as gone over, but will also contribute materially to enrich the land, by the folding of the sheep. In this manner, in fact, a plot of ground is gone over regularly by piece-meal, with as much uniformity as if undergoing the operation of the scythe. In certain situations sheep or cattle cannot be fattened during the summer months advantageously, owing to the innutritious quality of the herbage; but it will be apparent that in combination with the mixture described, the most inferior natural herbage may be successfully employed for fattening. But the ultimate effects of this course of management in such situations, as regards the improvement of the soil itself, are even more important than the immediate one of being able to put on flesh. It is evident that if persevered in for a time, whether the Flax-seed employed be of home or foreign growth, the fertility of the soil will eventually be permanently increased, by the production and application of the increased quantity of valuable manure which is thereby occasioned. Compared with such a system of manuring, the application of guano or any of the numerous fertilisers to which attention is now directed, is comparatively unimportant. It is an important fact to bear in mind that no manure can ever successfully enter into competition with that of the farm-yard, when of home production. Being a bulky article, however, its value is seriously diminished when it is to be conveyed any considerable distance; and hence the advantage possessed by the portable manures in this respect.—*J. Sproule.*

ON THE APPLICATION OF SCIENCE TO PRACTICE IN AGRICULTURE.

LAST year I made an effort to stimulate the farmers of Suffolk to adopt a system of experimenting on a cheap and easy scale, for the purpose of securing a multiplicity of facts by which men of science might be able to test their theories, and elicit the principles upon which a correct practice of Agriculture depends. More than a twelvemonth's additional experience has added to my convictions that very few farmers possess any just notion of what is meant by the application of real science to practice. I perceive, indeed, that the subject is commanding increased attention, and that numerous attempts have been made and are making with various success in the right direction; but still I think the application of science to practice ought to be advancing at a much more rapid rate than it is. I have already directed attention to some remarks of Sir John Herschel, in his popular "Discourse on Natural Philosophy," and I shall here extract another passage which places the difficulties in the way of applying science to practice, in a just point of view. I quote it as preliminary to a few remarks I wish to make upon some observations of practical men (which I have lately noticed), with reference to certain attempts which they consider to be failures, in the application of scientific principles to the improvement of Agriculture. "Art is the application of knowledge to a practical end. If the knowledge be merely accumulated experience, the art is empirical; but if it be experience reasoned upon and brought under general principles, it assumes a higher character, and becomes a scientific art." "Applications come late; the arts continue slowly progressive, but their realm remains separated from that of science by a wide gulf, which can only be passed by a powerful spring. The whole tendency of empirical art is to bury itself in subtleties, and to place its pride in particular short cuts and mysteries, known only to adepts; to surprise and astonish by results, but to conceal processes. The character of science is the direct contrary; it delights to lay itself open to inquiry, and is not satisfied with its conclusions, till it can make the road to them broad and beaten; and in its applications it preserves the same character, its whole aim being to strip away all technical mystery, to illuminate every dark recess, and to gain free access to all processes, with a view to improve them on rational principles. It would seem that a union of two qualities almost opposite to each other—

a going forth of the thoughts in two directions, and a sudden transfer of ideas from a remote station in one, to an equally distant one in the other—is required to start the first idea of applying science."

I lately noticed in the *Gardeners' Chronicle* my admiration of the bold attempt which Mr. Mechi has made to carry out the views of modern speculators in the improvement of Agriculture. I saw a notice this last week in one of our local papers that a practical gentleman has pronounced his attempt to be a complete failure, and he also states it is so considered to be by the whole of the neighbourhood. Possibly these statements may be somewhat premature; but still, if Mr. Mechi should prove an Agricultural Curtius, and by his vigorous hazard succeed in shutting to close the gulf which at present yawns between science and practice, his fearless devotion must command the respect of all who are not so apathetic to admire the zeal he has manifested for the interests of Agriculture. Very possibly some parts of his scheme have been injudiciously laid, and may be improved upon; and perhaps some of his calculations may have been grounded on insufficient premises. It is very possible, also, that whilst Mr. Mechi possesses a laudable faith in the abstract truths promulgated by scientific men, yet he may have fallen into a common error of practical men, in supposing that science is already sufficiently advanced to dictate to practice whatever may be executed on a grand scale. Now practical men must still be assured that the leap to which Sir John Herschel alludes has not yet been taken. Science is at present only training the athlete for the leap he must take if Agriculture is to become a scientific art; but she is not exactly requiring him to part with all his flesh and muscle, and so contrive to lose the stakes for want of strength sufficient to spur an unwilling horse. The method which science for the present proclaims to be most advisable for securing the advance of Agriculture, is that which I have so perspicuously pointed out in the several writings of some of her best mouth-pieces, viz., "experimental co-operation upon an extended scale." My schedules A are now coming in, and I already see with increasing conviction the importance of this plan. A gentleman devoted to Agricultural Chemistry was here at the beginning of this week, and he remarked to me that he had himself found how impossible it was to trust to the results of any one, two, or a dozen such experiments as those which must be tried. He admitted it is necessary they should be attempted by hundreds and by thousands. A correspondent in the *Agricultural Gazette* a week or two ago, sneers a little at "March of Intellect Men," and complains that some of their schemes have so far misled him as to have marched the profits off his farm. I suspect we must class your correspondent among those "Hist of Intellect Men" who so frequently verify the old proverb of "the more haste the worse speed." They fancy that some well-established principle in science will lead immediately to great practical results; and then they proceed to apply it according to their own conceits, in a way which insures to them abundance of disappointment. When they thus fall in their calculations, they fall in dudgeon with science, and sit down abruptly in "the seat of the scorner," and declare they will have nothing more to do with "new-fangled schemes."—*Ed. gr.* The value of liquid manure is now pretty generally acknowledged by gardeners at least, if not by farmers. It was asserted, many years ago, that its value was duly appreciated in the more advanced agriculture of some foreign nations; and some of our English farmers, with their usual enterprise, bought manure carts and dog tanks, and then failed in applying this manure beneficially. The tanks were filled up, and the carts allowed to rot. But it was mismanagement in the application which led to these failures. Science was right—foreign farmers were right—English inexperience was at fault. Within the last week I have heard of a farmer who built a large tank, about two years ago, and carefully filled it with liquid manure. He found it produce no beneficial result. My informant ascertained that he had delayed the application too long. He had suffered it to putrefy; and had not attempted to prevent the escape of the carbonate of ammonia; and had only applied it after it had become comparatively worthless. If farmers wish to see science successfully applied to practice, they must either obtain for themselves a sufficient knowledge of chemistry, botany, entomology, geology, &c., to enable them to perform the requisite experiments, or they must trust to the guidance of those who are acquainted with those sciences, as to the sort of experiments it is necessary they should undertake. A time will come when the leap shall have been taken, but, in the mean time, we can only say "God speed the Plough," as heretofore.—*J. S. Henslow, Hitcham.*

ON THE APPLICATION OF MANURES.

Admitting the accuracy of the principles I have advanced in these papers, the proper mode of applying manures is easily ascertained. Exhalers of manures—popularly so called. As the root has hitherto been considered the only inlet of nourishment to plants, the leaves have been treated of only as digestive organs, the ground has been considered the only storehouse, and we have closed our eyes to the evident indications of nature in the volatility of decomposing animal and vegetable matters. In a vain attempt to force these matters on the roots of plants, we have buried them at depths which we thought would prevent the escape of their effluvia. Now as their volatile parts are taken in by the leaves, in lieu of burying we should lay them on or as near the surface as to be accessible to our surface operations, which let loose the effluvia, while the plants are growing; and as a plant from its earliest growth, from the first sheeting of its plumule, takes in these effluvia, and as on a strong and vigorous early growth the future strength of the plant will much depend, a portion at least of these matters, in an advanced stage of decomposition, should be placed at or as near the seed as possible; guano may be usefully and, from its portability, steadily employed. Whether we think proper to top-dress a growing crop or not, frequent surface hoeings are requisite to keep up a continuous discharge of these effluvia from the soil. There can be no doubt that repeated, continued hoeing, by giving to the plant its food, must promote its more rapid development; but in order to continue these operations to a late period of its growth—for at a late period they are most valuable—we must make our rows at considerable distances, in grain crops at much greater indeed than we have been accustomed to do: from eighteen inches to two feet I think would give us distance enough; and from experiments stated hereafter, this will give a greater return of grain and straw than any other distances. At such a distance I feel assured a greater number of stems would be found in a given space of ground than would be in a broad-cast or narrower drilled crop, and these would carry a better head, have a more standing crop, be reaped with greater facility, and, from the absence of weeds, be carried much sooner. But the advantages of a wide row system are not confined to the growing crop—they extend to future and far distant ones. Apart from the cleanliness produced, the constant fallowing process so opens the soil, as to induce the solution by the atmosphere of those inorganic bases which are required by plants, and the want of which makes the alternation of crops necessary; the soil may thus, by this thorough cultivation, be made to bear the same crop successively, or at shorter intervals; or, which amounts to the same thing, to yield a heavier return in the course. The dews and light rains, instead of evaporating, enter the soil to assist the chemical changes, provoked by the moving of its parts; light pervading all the spaces between the plants, in these wide rows, enables the leaves to appropriate and decompose the carbonic acid of the air. In the country from which I write, the general adoption of the wide-row system would be necessarily attended with peculiar public good. Here there is a want of capital, which alone frequently places a difficulty in the way of the small farmer, in seeding his ground, and often delays him till the proper season is past; and from this a want of employment follows. Here in the wide-row system a remedy, to a considerable extent, is at hand. The value of the excess of seed, which is everywhere shed over the ground, would pay for an amount of manual labour that would leave none but the will-be-idle unemployed throughout the growing season of the year. From three-fourths to two-thirds of the seed would be saved, and this alone is a national object.—*J. M. Goodiff, Granard.* —— P.S.—About twenty-four years ago a small plot of ground was sown with Barley—it was divided into five equal parts; on the first, the seed was thrown broadcast by the hand; on the second, it was sown in rows 7½ inches asunder; in the third, 15 inches asunder; in the fourth, 22½ inches asunder; and in the fifth, 30 inches asunder. The produce both in grain and straw (separately), was carefully weighed as soon as possible after being cut. No. 1 gave the least return in both Corn and Straw, Nos. 3 and 5 gave an equal return, but more than 1 and 2; and No. 4 gave the greatest return of both. The distance between the rows in this case from which the greatest return was derivable was between 15 and 30 inches. The following year a strip of Lammas Wheat was sown, chiefly with a view of ascertaining how late Wheat might be sown in wide rows; on the 25th March in rows 22½ inches asunder, in a field where the same description of Wheat was sown the November previous in drills 9 inches asunder, the strip of wide rowed Wheat was reaped before the rest of the field was carried, say within ten days after the rest was reaped (it is the custom in Ireland to leave the Wheat in field-stacks some short time, generally till the whole is cut and fit to be carried). When the wide-rowed strip was in stook, I drew at random five straws from it; I did the same from the stacks of five or six Wheat-fields in the neighbourhood, and with private marks to the samples I showed them to several farmers; they all were of opinion that the wide-rowed sample was the best. I have this year nearly half a statute acre of Chevalier Barley sown in rows 18 inches asunder, with the exception of one patch 15 yards by 6 yards, sown at 9 inches; this has not been hoed but hand-weeded; the rest has been hoed three or four times; the patch was at once distinguished some time before harvest by the lightness of its green. The wide drills were sown at the rate of six stones to the statute acre in the middle of May (could I have sown it in April I would not have given more than three or four stones to the acre); in the patch a double quantity of seed was sown—that is at the rate of 12 stones to the statute acre; yet I do not think there are more stems in it, and I would challenge any broadcast field to produce more of good Corn. Notwithstanding the late rains it is a standing crop. When the crop is cut I will forward a statement of its produce. [Thank you.]

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Harvesting.—East Lothian being somewhat celebrated as a Corn-growing county, a brief description of its mode of harvesting, or manner of cutting and securing grain-crops, may prove acceptable at this season, before noticing the cultivation of individual crops.

There is some diversity of opinion amongst agriculturists respecting the degree of ripeness necessary before cutting down Corn, but the practice of the best farmers in this county appears to sanction the performance of this operation before the grain and straw become dead or thoroughly ripe: grain-crops, particularly Wheat, are therefore generally cut before attaining perfect maturity. The common criterion of sufficient ripeness, as indicated by the straw, is when it begins to shrink and become white about an inch below the ear. The circulation of sap to the grain is then cut off, and all further benefit arising to the crop from remaining longer uncut is consequently terminated.

Although the scythe is now, and has been for many years, much employed by some farmers, reaping, or shearing, as we here term it, with the sickle, is by far the most general mode of cutting down the Corn-crop. There are two kinds of sickles made use of—the serrated and the smooth-edged or scythe-hook; the latter is generally preferred, as being more expeditious and less difficult to work with than the former; but as the farmers now find it extremely troublesome to prevent the reapers, when the scythe or smooth-edged sickle is used, from cutting down the crop in a peculiar manner, termed *slashing*, which is at the best but a very imperfect and objectionable process, strictly prohibited by good farmers, the serrated instrument is again coming into general use. Low reaping is particularly insisted on, and, generally speaking, everywhere practised. Some farmers are in the habit of giving a small additional allowance, as an encouragement or reward to such reapers as have, during the course of the harvest, executed the lowest and cleanest work. The ridges being usually 18 feet in breadth, three reapers are placed upon each of them; one man, denominated a bandster, binds and stooks the sheaves to six reapers.

In ordinary cases, the stooks, or shocks as they are in some places termed, are made in every alternate ridge; but when the crop is light, two neighbouring bandsters often stook together. In the case of Wheat, six pairs of sheaves make a stook; but when the crop is Oats or Barley, the stook may consist of only two, three, or four pairs of sheaves, according to the state of the weather and the inclination of the farmer. In many places two hooding sheaves are placed on the top of each stook to protect the grain from the effects of inclement weather; but they are here entirely omitted, of whatever kind the crop or season may be. As binding and stooking are operations of the greatest importance, to which too much attention cannot be devoted, none but the most careful and expert are employed in that department. The stooks are invariably set in a direction from north to south, that the sheaves may be equally dried on both sides.

Small-sized sheaves are always preferred, but especially when the crop has been cut rather prematurely, or in a damp state. In general cases, the binding and stooking are carried on simultaneously, but it frequently becomes necessary in this county to cut part of the crop in a wet condition; and in this case, instead of the usual method of binding, the sheaves are loosely tied near the corn-ends. Each sheaf stands singly on its own basis, the bottom being drawn out in a circular manner to maintain it erect. This operation is termed *gaiting*. It is applicable only in the case of Oats and Barley, and being attended with a considerable deal of after-trouble, is never resorted to except when the Corn is cut while in a damp state. When ready for stacking, the gaits are all firmly bound in the usual manner, and either conveyed immediately to the stackyard, or stooked in the field until it becomes convenient to remove them.

Reaping with the sickle is decidedly the most general mode of cutting down grain crops in this county; but the scythe, as already observed, has been long though partially employed for the same purpose, and is, on the whole, gaining ground, as with it the straw is cut much closer to the ground, and the whole operation performed more cheaply and expeditiously than can be done with the sickle. The principal objections here urged against mowing grain-crops are—that the Corn is not laid down with the same regularity, nor the ears made to lie in one direction, so uniformly as when the sickle is used; that the grain is more liable to vegetate and sprout while in the stook, in moist weather; that the stack of mown sheaves has a rougher appearance; and exposes more grain to the weather and the depredations of birds; and that mown sheaves are more difficult to be threshed, either by the flail or threshing-machine. It is contended, on the other hand, by the advocates of scythe-cutting, that the irregularity and imperfection imputed to mowing arise chiefly from the want of skill, dexterity, and care on the part of the mower and his attendants; that a man can bind and stook one-fourth more sheaves in a given time, when mown, than he can when reaped; that mown sheaves dry quicker, and are ready for stacking several days sooner than reaped ones; and, above all, that the scythe possesses a great superiority over the sickle in point of economy and despatch. In Aberdeenshire, and some others of the northern counties of Scotland, the whole of the grain-crop is mown without exception, and the labourers there have acquired, from continued practice, much dexterity in the use of the scythe. A considerable quantity of Oats was last year mown by Aberdeen men, in this county, and the farmers appear anxious to introduce and extend the practice. The usual custom is for the farmer to contract with one man for performing the mowing, lifting, binding, stooking, and raking per acre. This man, who engages to have all these operations executed to his employer's satisfaction, hires a sufficient number of persons—men and women—from his own country to cut all the Corn he can obtain. A contractor, or undertaker of this kind,

has generally several sets of mowers and their attendants working at the same time, on contiguous farms. Numerous contracts have been made for the present harvest, not only in this, but in several other counties in the south of Scotland.

The scythe employed by the Aberdeenshire mowers, and which is expected soon to become general throughout this county, differs considerably from the common one in the shape and length of the handles. It has two short handles, one projecting from the other, which, by placing the operator in a less constrained position, render it more easily worked than the common one. This scythe has no cradle or other appendage; each mower is attended by a woman, to make bands and place the Corn in sheaves upon them, and a man immediately follows to bind and stook the sheaves. A stout boy provided with a large corn-rake having curved iron teeth, can rake to three scythes.

Reaping by the sickle is also sometimes, but not frequently, performed by contract. The county is abundantly supplied with reapers from Ireland and the Highlands; they are hired by the week, and paid according to a certain rate of wages agreed upon by the farmers at weekly meetings held at Linton and other places. The average rate of wages for reapers during the last few years has been about 9*s.* a week, not including their diet, which is commonly reckoned at 8*d.* per diem. In the generality of farms, four men are considered to be capable of cutting and stooking an acre of Corn on an average daily throughout the harvest; these, at 1*s.* 6*d.* each per day for wages, and allowing 6*d.* for diet, make the expense of reaping with the sickle 8*s.* 8*d.* per acre. The cost of cutting with the scythe is considerably less: a good mower will cut down 1½ acre of Wheat, or 2 acres of Oats or Barley, of an average quality and not much laid, in 10 hours. Taking the Oat-crop for an example, the cost of mowing, binding, stooking, &c., 2 acres, will be as follows:—

1 man (mower)		2*s.* 6*d.*
1 man or woman (gatherer)		1 6
1 do. (binder)		1 6
1 man can rake to three scythes		0 6
Wages	5 6	
Diet	2 6	
Cost of cutting 2 acres	8 0	
Do. of 1 acre	4 0	

—*T. Sullivan.*

(To be continued.)

Home Correspondence.

Drainage.—In looking over the strictures of "A Farmer and Valuer," on my remarks on the Report of the Debenham Farmer's Club, the first thing that strikes me as extraordinary, is that an individual, who it would appear is unwilling to give even the authority of his own name to his statements, should expect that his *ipse dixit* would affect the observations which I made, backed as they were by what I conceive sound reasons and the experience of the best practical drainers in this or, I will venture to say, any other county. As I conceive it to be the duty of every individual to contribute his mite to the overthrow of error, and as I think the cultivation and use of "plashings," as practised at Debenham, a most grievous agricultural error, I shall make no other apology for criticising the remarks of your Stowmarket correspondent. He complains of tile drains becoming choked with clay, but it must be evident to every one acquainted with the subject, that that is the fault of the execution of the drains, not of the tiles, as no well executed tile drain can have "clay worked into" it; indeed, from the very nature of clay, there is no kind of soil in which drains are likely to last so long, and there are many tile drains in this county, but especially in East Lothian, in all varieties of soil, from plastic clay to sandy loam, which have been in use for twenty years, which are found to work as well as they did when newly put in. I would recommend to "A Farmer and Valuer," the next time he is induced to try tile-draining, whether by "chance or otherwise," to put the tiles out of the reach of any working whatever. One of the reasons given by your Stowmarket correspondent in favour of his much-loved "plashings" really deserves the epithet—ludicrous; it is, "that it," that is draining with straw and plashings, "has been in use in their county for nearly a century, and found very beneficial." I have no doubt his ancestors in the days of yore found it very beneficial to live in a cave or a hut, but that is no argument against the use of a modern house. Does your correspondent carry out his principle by grinding his Wheat in a quern, in preference to what I presume he will term "march of intellect" nonsense—a flour-mill? Is his plough a crooked tree? Does he prefer the ancient wild breeds of cattle and sheep to the short-horn and new Leicester? All these had the merits of ancient usage, and of being beneficial in their days; that day has gone by. I have no patience with men who rail at what they are pleased to term the "march of intellect;" they ought to know that it is to this that their country owes the status which she holds; that it is by this that we are enabled to maintain a population our fathers never even dreamed of; that it is to this, under Providence, that they are indebted for a large proportion of their comforts and enjoyments. Your correspondent says "that he does not pretend to know how the water gets into the drains, except that it will run down hill." What an extraordinary operation the draining of a perfectly level field must be to him. I consider the quotation from Mr. Smith's work on the advantages of draining parallel to the declivity, quite unanswerable, and every one acquainted with the literature of agriculture knows that he, as well as the other writers whose opinions I quoted, are practical men; the words about "written theories" were altogether misplaced. I am not at all surprised that a field drained in any way with "plashings" should not be dry; and with regard to the portion drained obliquely, I think your correspondent's statements very ingenious; but if I had found the water running down the furrows till it fell into the drains, I would have been inclined to call it all equally wet, instead of dry. It would appear that he has some indistinct notion of another way by which water gets into drains besides running down hill, notwithstanding his assertion to the contrary, for he says "that unless the drains are made not further than six or seven yards apart, the water will not *draw* into them." I happen not to have the Number of the Royal Agricultural Society's Journal by me, referred to by your correspondent. Does he mean to assert that Mr. Pusey advocates the cultivation and use of "plashings?" In conclusion, I have just to say what I asserted before that tile-draining was nearly as cheap as that with straw, and I now assert, in consequence of information regarding some of the new tile machines, that in a country where clay can be got, tile-draining is cheaper; and I would give "A Farmer and Valuer" an advice I often see in the *Gardeners' Chronicle*, that no one should write about things they do not know about, far less about what they do not even pretend to know about.—*J. Girdwood, Featherhall, Midlothian.*

Allotments.—Since addressing you on the allotment system, I have read with pleasure a letter published in a provincial journal, from Sir R. Bunbury, calling upon the landowners in West Suffolk to form a society for the alleviation of the distress of the working classes. I am rejoiced to find that one of the modes proposed to effect this object is the allotment system, under the direction of a committee of management, whose duty it will be to provide land for the labourer at a fair farming rent, and not at the exorbitant price generally demanded for small patches of ground. Should the praiseworthy example of West Suffolk be followed by other localities, it will be the means of extricating the poor man from the rapacity of his neighbour, having land to let out, but too idle to work it himself. I have often looked with pity on the labourer, who, after having hardly earned his daily bread by the sweat of his brow, has repaired to his allotment to expend his remaining strength in the vain hope of raising a few Potatoes for winter consumption; when I knew that his utmost exertions would barely enable him to pay the rent, leaving nothing either for himself, or to purchase manure for the following spring, or buy a pig to assist the muck-heap. The allotment system, to answer a benevolent end, must be based on equity, giving the small tenant every facility for turning his lot to the best account, instructing him how to procure the cheapest manures, and how to use them to the best advantage. As you have, in your notices to correspondents, expressed a determination to bring the allotment system fully before the public, I think I cannot leave it in better hands, and will, therefore, not trouble you again on this subject, unless anything unusual calls for remark.—*Falcon.* [We shall always be glad to assist our correspondent, and others interested in the allotment system, in keeping alive a discussion on this subject by the detail of facts and arguments not hitherto published. It is a subject which should be kept constantly before the public.]

Failure of Crops.—We are all in despair in this neighbourhood; the most flourishing of the early sown Turnip crops are daily disappearing. We hope in the next *Agricultural Gazette* for advice on this serious calamity, as it is a most unusual cause of destruction which I am about to describe; and we trust you will suggest remedies, either to arrest the ravages of the insects, or prevent the evil from spreading so rapidly, should it appear next season. About a week since the weather was cloudy, cold, and windy, and suddenly the ground was partially covered with innumerable minute frogs and toads, and the Turnips appeared to have received a check in their growth. At this period my crop was very flourishing; in a day or two the finest plants withered in patches, and now the evil seems almost hourly to increase. The complaint, I grieve to say, is very general, and as no remedy seems to be known, what would you advise being now sown to replace this valuable crop? I send you specimens of the different insects, in the several stages of existence; pray name them, and describe their habits—how they may be destroyed, and in which state they commit the greatest devastation. We observe the Swede suffers less than the Turnip; and where Charlock abounds it is first attacked. —*A Cotswold Farmer.* [We do not know how to help you. Cabbages (the early York), Rye, and Vetches are, as you probably know already, among the earliest of our spring crops. How would it answer your purpose to purchase young Savoy plants of the market-gardeners, and prick them out in your Turnip-beds? They would be ready about Christmas. Your insects have been sent to *Ruricola*. The subject of this communication is a most important one, and any practical farmer who has any suggestion to make, would benefit his "neighbours" by communicating it through us.]

Farm Implements.—After your remarks on the Improvement of Agricultural Mechanics, I wish you could inspect the simple implements which enable 22 persons to gain their living in comfort on 13 acres in my neighbourhood, and two of these families, who had been in the Union-houses of Hallingly and East Bourn, to become rate-payers instead of rate-receivers. They have not a plough amongst them; the 3-pronged fork, 14 inches deep, which the late Dr. Yelloly recommended to the Statistical Society at Liverpool, is better to stir the ground than any plough; and the seed is put in admirably straight lines by a hoe—the Vernon hoe—the seed being deposited by children; and where there are hands enough to do this work, can the most perfect machine moved by a horse be so advantageous, either for the individual occupier or the community, as manual labour? For, by the law of the land, all human beings in England who cannot support themselves must be supported out of rates levied on the land, before one farthing can reach the owner as rent. Witness Chelmsbury, as quoted in your Paper some time since. Why not, then, lessen those rates by letting willing hands do all the work that is within their power? for horses need not be kept—men must. Large farms have been the fashion of late years. Will large farms, with fine agricultural machines, drawn by fine horses, yield most rent, or send most produce to market? On the contrary, my little tenants, without a plough, harrow, or any animal of draught, have for a series of years paid me more rent than my greatest tenants. In 1840 I took in hand 1000 acres from a tenant, who also had a better farm in occupation in another parish, to learn why my rent was so low and the poor-rates so high; and I think an investigation into the result would be worth your pains. Not long ago, J. Harrod, of Pevensey, who was in the Hallingly Union in 1840, told the Earl of Devon, who came from London on purpose to see him and other allotment tenants, that he was supporting his family and wife and four children in comfort on three acres, and hoped soon to have nothing but salt to buy for them; and since then, he has reaped his Corn, and says he is satisfied any man can get his living on three acres. My having employed more manual labour on this 1000 acres than my tenant did, and let about 26 acres for spade husbandry, has lowered the rates from 5*s.* 3*d.* to 2*s.* 6*d.* in the pound; and, by the same means, the rates have been similarly lowered in other parishes. By the general adoption of my system, the incendiary fires which raged in Sussex in 1830 would cease, and the Income-tax be rendered unnecessary, and 5,000,000*l.* out of 7,000,000*l.* of the rates in England and Wales would be saved by the produce of a greater quantity of human food raised by the prong than by the plough.—*M. A. C.*

Egyptian Wheat (Triticum compositum).—I send you the inclosed sample of a small patch of Egyptian Wheat, obtained by dividing and transplanting from 9 grains, so very diminutive and poor, that for a time I thought it useless to put them into the ground. I have beaten out the grain from five ears, and I find in the smallest 70 grains, and in the largest of them 176 grains. I am not a judge of the quality of the grain, but I think it has been somewhat injured by being cut a day or two too early. The straw is about 5 feet in length; the piece I send is cut from the second joint from the root.—*Henry Moule.* [The ear sent is a very fine specimen of the variety.]

Analysis of Onion.—In answer to Mr. Jackson's query as to the mineral ingredients of the Onion, allow me to state that Fourcroy and Vauquelin found in it sulphur, citrate of lime, and phosphate of lime. There is also reason to believe that it contains much muriate of potash.—*G. W. Johnson.*

Preparation of Seed.—I have, this year, a field of Oats, the centre part of which was drill-sown with seed that had been steeped for 24 hours in the contents of a cess-pool (in which the water from the cow-byer, stable, &c. collects), and subsequently sprinkled in the usual way with lime: on one side of this centre portion the corn was sown by the hand, and on the other drilled, the seed being, in both cases unprepared; the result has been that the plants from the prepared seed have not one single blighted, or black head of corn; but on both sides of it, where the seed was unprepared, they abound. The seed was thrashed from the same stack, the land in the same state of culture, and sown the same day.—*F. D. Johnson, Aykleyheads, near Durham.*

Egyptian Barley.—A young friend of mine had six grains of Egyptian Barley given her last spring, which she planted in her little garden about three inches apart. They have tillered greatly, and now the produce amounts to 70 good ears of six-rowed Barley, of about 63 grains each. Call it 60 only, and here are 4200 grains from 6 grains, or 700 for one.—*S. H.*

Potato-crop.—I have read in your Paper the communication of one correspondent who attributes the failure of this crop to the tubers being unripe as one cause, and this I know from experience to be erroneous. About 33 years ago, I lived in a district where a considerable breadth of land was annually planted with early Potatoes for the Manchester market; and about the end of June, when the small Potatoes were not disposable at market, the Potato-growers picked the largest of the small ones out, and threw them on the ground a few days to harden, and to green a little by exposure to sun and air. Finding them after this to answer the purpose of seed well, I adopted the practice, and have ever since saved the seed Potatoes from the earliest and second sorts in this manner, and have not had one failure in the whole time. This year I planted from seed saved this way at various times from the beginning of April till the middle of June, and in all the various plantings, although the shoots of some of the latest had been broken off twice, previous to planting, I have not one in a hundred that has not come.—*J. Jackson.*

Chemical Analysis.—Can you not urge for general adoption what I have suggested here, "that Agricultural Societies should employ a chemist, who, at a certain fixed rate, should analyse soils and manures for

all members of the Society—the member paying one-half of the expense, and the Society the other?"—*A. L. M., Lincoln.* [This is just what we have taken every available opportunity of advocating.]

Produce of Wheat.—At the end of August, 1843, I planted in my garden 32 grains of Wheat, at 6 inches distance, an inch and a half deep; the seed was of the first-rate quality. This seed produced this year 32 plants, having from 10 to 28 stems and ears each; the average number of ears was 16; the average weight of each plant 12 ounces. An acre of land would contain, at 6 inches distance, 174,240 plants; the produce 304,920 oz., or nearly 9,000 lbs., or 320 bushels, or 40 quarters per acre. The expense of sowing would be more than half of the diminished quantity of seed required. I do not wish to state that such a result would be obtained upon a large scale; but I think it is worthy of trial, when we know that the average produce is only 22 quarters per acre, and that it is possible (?) to grow 40: it will be allowed that there is ample scope for improvement. Try a breadth of your fields an inch and a half deep; put 1 grain, and 1 only, in each hole—plant it at 6 or 8 inches distant—be sure to plant good seed—get as much produce as you can, but go for 40 quarters per acre.—*Bath Herald, August 22.*

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY OF ENGLAND.

The Council stood adjourned to Wednesday last, the 4th of September, but no meeting was held on that day, in consequence of the absence of members from town. The adjournment accordingly now stands over the autumn recess, until the 5th of November, when the meetings will be resumed.

Gossip.—Lord Kenyon having announced to the Duke of Richmond, as President of the Society, his intention to give a Prize of Twenty Sovereigns, at the ensuing country meeting at Shrewsbury in 1845, for the best Essay on the subject of Corn as food for cattle, &c., the following schedule of the terms and conditions of that Prize have been received from Philip Pusey, Esq., M.P., Chairman of the Journal Committee:—"Twenty Sovereigns, or a piece of plate of that value, offered by the Rt. Hon. Lord Kenyon, will be given at the Annual Country Meeting of the Royal Agricultural Society, to be held at Shrewsbury in 1845, for the best account of the use of Corn for the food of cattle, horses, or sheep, founded on actual experience. Competitors will be required to state the following points:—

1. The quality of land on which the Corn is grown.
2. The age of the plant when cut.
3. The mode and expense of cutting.
4. The mode and expense of preparing for food.
5. The mode of feeding with the Corn, and the quantity of other food given therewith.

All Essays competing for this Prize to be sent to the Secretary of the Society, No. 12, Hanover-square, London, on or before the 1st of May, 1845."

The Society have received from Mr. Barton a communication on experiments relating to the application of Sulphate of Ammonia to the Growth of Wheat; from Mr. Towers, a further statement of his results from Dibbled Wheats; from M. Hugues, of Paris, a memorial addressed to the President, calling the attention of the Society to his new Drill, and soliciting a practical trial of its merits; from the Hon. Robert H. Clive, M.P., Vice-Chairman of the General Shrewsbury Committee, and Mr. Poole, town-clerk of that borough, communications on the subject of the facilities intended to be afforded in the conveyance of passengers and stock to the Shrewsbury Meeting, and the preparation of the 20 acres of light and 20 acres of heavy land, in the immediate vicinity of the town, for the trial of implements; from the Rev. Dr. Buckland, a copy of the Address delivered by him at the Southampton Meeting to the Mayor and Members of the Artesian Well Committee; from Mr. Hillyard, of Thorpelands, near Northampton, a copy of the new and enlarged edition of his work on Practical Farming and Grazing, dedicated, by special permission, to H.R.H. Prince Albert; from Mr. Morton and Mr. Atkinson, communications on a proposed reduction of the meteorological observations made extensively throughout the country, under the direction of Mr. Morton, with a view to ascertain the practical value of the rules for predicting changes of weather, contained in the Essays competing for the Society's Prize of the Gold Medal; from Mr. Wyon, R.A.'s Chief Medallist, announcing the completion of the medals struck at the Royal Mint for the Exhibitors at the Southampton meeting, to whom they had been awarded; from Mr. Shaw, copies of the "Farmers' Magazine;" from Mr. Youatt, copies of the "Veterinarian;" from the Royal Asiatic Society, the last Part of their printed proceedings containing notes on Indian Agriculture; from the Royal Agricultural Society of Ireland, a copy of the Essays on the Cultivation of the Sugar-cane, written in competition for the Earl of Elgin's Prize of 100*l.*; from Mr. Mann, a copy of his work, descriptive of the Bee and Frame Hive invented by him; from Mr. Oakes, a copy of the Prizes of the South-East Kent Association, for the encouragement of industrious and meritorious Agricultural Labourers; from Mr. Allen, copies of the "American Agriculturist;" from Mr. Lillie, a copy of his Agricultural Tour in Ireland; from Mr. Peter Hulme, of Philadelphia, a most interesting collection of American Agricultural publications, presented to the Society by Mr. Edmund Ruffin, of Virginia; and from Mr. Palmer, of Axminster, the 24 Number of the "Western Agriculturist," containing the continuation of the Rev. W. D. Conybeare's contribution on Agricultural Chemistry.

FARMERS' CLUBS.

Gloucester.—The following paper on The Best and Cheapest Means of Carrying Stock through Winter during Scarcity of Hay and Roots, was read by Mr. Gyde, of Painswick, at the late meeting of this Club.

My object is to draw attention to those substances produced on the farm, which are capable of being substituted for hay and roots as food for cattle, and to point out the quantities which practice, as well as science, would indicate as equivalent to good meadow hay, in feeding properties. In a paper which I formerly read before you, I showed you how the doctrines of Animal Physiology might be applied to the feeding of cattle. It will be necessary to briefly review the leading points then alluded to. The body of an animal may be divided into three distinct classes of matter, namely, the muscular portion, including all those structures containing nitrogen; the fatty portion, which is devoid of nitrogen; and the earthy and saline portion, consisting of saline matter and bone. Until within the last few years physiologists supposed that the food underwent, in the stomach of the animal, some change during the process of digestion; that the stomach, in fact, had the power of making out of the Grass and roots taken as food, those substances of which its body was composed; this power they termed the *vis vitæ*. But the investigations of modern chemists show that no chemical alteration takes place in the constituents of substances during digestion, but that the elements of the animal body are prepared and elaborated in the vegetable. In the vegetable, we find a principle identical in composition with the muscle of the animal, and known as gluten, vegetable albumen, and casein. We have carbon for combustion in the lungs, to keep up animal heat, supplied in the starch, gum, and sugar of the plant; and we have also oil for the purpose of forming fat, with earthy and saline matter for the bone and blood; these substances are all that the animal requires, of which to build up its structure. This being admitted, it only becomes necessary to ascertain the amount of those constituents of the body daily thrown out of the system by the various channels of waste, to enable us to point out, with some truth, the quantities of each substance necessary to replace the daily loss in the animal economy; or, in other words, to say how much gluten and starch of the vegetable will be required to supply the waste of muscular and other constituents of the animal. Practice says that an ox requires 2 per cent. of his live weight in hay per day; if he works, he requires 2½ per cent.: a milch-cow, 3 per cent.; a fatting ox, 5 per cent. at first, 4½ per cent. when half fat, and only 4 per cent. when fat; or 4½ on an average. Sheep grown up, take 3½ per cent. of their weight in hay per day to keep in store condition; and growing animals should never be stinted. Science has ascertained, by the most carefully-conducted experiments, that a full-grown man voids, in his urine alone, about ½ oz. of nitrogen every 24 hours, and that a small quantity passes off in the solid excretions and by the skin. The carbon consumed by the lungs to keep up animal heat, averages about 11 ounces in the 24 hours; and the saline and earthy matter voided is in direct proportion to the amount taken in the food. It appears that the food consumed by an ox, horse, or sheep, is in direct proportion to their weights when compared with man. Hence we find that an ox would require, to replace the daily loss of muscular fibre, from 20 to 24 ounces of dry gluten or vegetable albumen, which would be supplied in

120 lbs. of Turnips	17 lbs. of Clover-hay
118 lbs. of Wheat-straw	12 lbs. of Pea-straw
75 lbs. of Carrots	12 lbs. of Barley
67 lbs. of Potatoes	10 lbs. of Oats.
20 lbs. of Meadow-hay	5 lbs. of Beans

The consumption of carbon by a cow amounts to 70 ounces; and that of a horse to 89 ounces on an average in 24 hours, which is supplied by the starch, gum, and sugar of the food consumed. Fatty matter is required to supply the fat of the animal, and this also exists more or less abundantly in all vegetable food. Earthy phosphates and saline substances are found in the inorganic portion of all vegetables, and these supply the daily waste of bone, &c., of the body. Hence we see that the animal requires a variety of substances, all of which exist in greater or less abundance in its daily food. In one article of diet we find one substance in abundance, and in another other substances. Thus, farinaceous seeds are made up of starch and vegetable albumen or gluten, with much fatty matter and phosphates. In the oily seeds, as Lint-seed, Hemp-seed, &c., the predominating ingredient is oil, and matter called casein, which is capable of supplying muscle. In the Potato, starch is the ingredient in greatest quantity, combined with vegetable albumen. In the Turnip, sugar and gum supply the place of starch; and in the Grasses and Clovers, woody fibre with albumen, a little starch, and much saline and earthy matter. From a knowledge of these facts, with the assistance of the accompanying Tables, which show the quantities of water, woody fibre, starch or gum, gluten, albumen or casein, fatty matter, and saline matter, contained in 100 lbs. of most of the products of the farm (see Table, No. 1), and the amount of these constituents contained in the produce per acre (see Table, No. 2), the judicious feeder will be enabled so to mix those crops which he has at his command, as to render everything available as food. He may keep his stock in condition by supplying with gluten, starch, and saline matter, the natural waste of the body, or he may fatten, by increasing the amount of food, particularly those articles containing much fat; always remembering that a mixture of food is better than confining to one article of diet, since it rarely occurs that one contains all those substances required by the animal, and without which healthy and vigorous life cannot be sustained for any considerable time.

TABLE I.—Showing the Composition of 100 parts of the more commonly cultivated crops.

—	Water.	Woody Fibre.	Starch, Gum, or Sugar.	Gluten or Albumen.	Fatty Matter.	Saline Matter.
Wheat	16	15	65	10 to 15	2 to 4	2.0
Barley	13	13	70	12	2.5	2.0
Oats	15	10	42	14.5	4.5	2.5
Rye	13	15	60	12	3.0	1.0
Indian Corn	12	15	70	7	5	1.0
Beans	14	15	40	25	2	3.0
Peas	13	14	50	24	4	2.0
Potatoes	75	2	17	2.25	0.2	1
Turnips	85	3	10	1	0	1
Carrots	85	4	10	1.5	0	1
Meadow Hay	14	28	30	7	4 to 6	8 to 10
Clover Hay	14	25	40	14.5	2.0	3
Pea Straw	10 to 15	25	45	12.3	4.5	5
Oat Straw	12	25	37	4.7	2	2
Wheat Straw	15 to 18	30	30	3.5	2	2
Barley Straw	do.	30	30	3.5	3	3
Rye Straw	do.	30	35	4.5	3	3
Indian Corn Straw	12	25	50	3.0	2.7	4

TABLE II.—Average Produce of Nutritive Matter of different kinds from an acre of the usually cultivated crops.

—	Gross Produce.	Husk or Woody Fibre.	Starch, Gum, Sugar, &c.	Gluten, Albumen, &c.	Fatty Matter.	Saline Matter.
	bush.	lbs.	lbs.	lbs.	lbs.	lbs.
Wheat	25	1500	225	150 to 220	30 to 60	30
—	30	1800	270	180 to 260	36 to 72	36
Barley	35	1800	970	245	45	36
—	40	2100	315	280	52	42
Oats	40	1700	340	230	95	50
—	50	2100	420	280	110	75
Rye	25	1200	180	120	40	12
—	30	1500	150	200	48	18
Indian Corn	30	1800	270	210	90 to 170	27
Buckwheat	30	1300	320	180	5	21
Beans	25	1500	150	450	32	48
—	30	1900	190	530	36	57

	tons.					
Potatoes	6	12,500	675	1620	45	120
—	12	27,000	1350	3240	90	210
Turnips	20	45,000	1350	4500	?	400
—	30	67,000	2010	6700	?	600
Carrots	25	50,000	1500	3500	1750	500
Meadow Hay	1½	3400	1020	1360	70 to 170	220
Clover Hay	2	4500	1120	1800	135 to 225	400
Pea Straw	—	3700	675	1200	40	135
Wheat Straw	—	3000	1500	900	15	150
—	—	3600	1800	1080	18	180
Oat Straw	—	3700	1210	958	30	135
—	—	3500	1470	1190	38	175
Barley Straw	—	2100	1050	630	15	105
—	—	2500	1250	750	20	125
Rye Straw	—	4800	1800	1500	20	1200
—	—	4800	2300	1800	24	240

TABLE III.—Showing the relative value of different articles of Food, as ascertained by practice; good meadow Hay being taken at 100.

Hay	100	Carrots	250 to 300
Clover Hay	80 to 100	Turnips	300
Green Clover	450 to 500	Cabbage	200 to 300
Wheat Straw	400 to 500	Peas and Beans	40 to 50
Barley Straw	200 to 400	Wheat	50 to 60
Oat Straw	200 to 400	Barley	50 to 60
Pea Straw	100 to 150	Oats	40 to 70
Potatoes	300	Indian Corn	50
Old Potatoes	400	Oil Cake	30 to 40

The above Table represents the average results from a number of experiments made in France and Holland.

TABLE IV.—Showing the amount of different articles of food of equal value as indicated by theory; good meadow Hay, being taken at 100.

Hay	100	Turnips	600
Clover Hay	90	Carrots	350
Vetch Hay	95	Cabbage	500 to 600
Wheat Straw	320	Peas and Beans	30 to 35
Barley Straw	350	Wheat	95
Oat Straw	450	Barley	60
Pea Straw	60	Oats	80
Potatoes	300	Indian Corn	60
Old Potatoes	400	Oil-cake	35

This Table represents the supposed value as food of the different articles, calculated from the amount of nutritive or fattening principle, they are capable of yielding to the animal.

Reprints.

The Alpaca, its Naturalization in the British Isles considered as a National Benefit, and as an Object of immediate Utility to the Farmer and Manufacturer.

By William Walton. Blackwood & Sons, Edinburgh.

For most of our cultivated plants, and indeed for many of our domestic animals also, we are indebted to other countries. With regard to the former, the history of their introduction is in many cases well established in detail; but it is so long since the latest of them, the Potato, the Turnip, or the Mangold Wurzel or Carrot, for instance, was first cultivated in our country, that farmers have fairly settled down into the belief that they must make the best of the subjects they have on hand, for that Nature has nothing further in her stores suited, in our climate, for the wants of man or beast. And with regard to the latter, the introduction of the very latest dates so much further back, that we must estimate the prejudice as stronger still which scouts at the idea of any further addition being made to our stock of domestic animals from the store of other countries. Of course, in speaking of this universal prejudice, we allude simply to the generality of those who at present occupy and cultivate our soil, and who form their opinion probably without very well knowing the grounds upon which it rests.

There is every probability, notwithstanding the general notion to the contrary, that a useful addition will shortly

be made to our stock of domestic animals. The Alpaca, from the experience of it which has been compiled from various quarters in this country by Mr. Walton, really seems likely hereafter to play an important part in the stock-farming of the hilly districts of the kingdom. This animal is indigenous in the mountainous regions of Peru, where two domesticated species of it occur. The one receiving the name of Llama is used as a beast of burden; the other—the Alpaca—to which we at present allude, is a wool-bearing animal, and of it large flocks were formerly possessed by the Incas, sovereigns in former days of that country, and by other wealthy inhabitants of it. The climate of the districts in which this animal flourishes is described by Mr. Walton as follows:—

"The woolly native possess a hardiness of constitution, and a goodness of structure, admirably well adapted to the nature of their birthplace. There, during half the year, snow and hail fall incessantly, whilst in the higher regions, as before noticed, nearly every night the thermometer falls below the freezing point, and the peaks, consequently, are constantly covered with an accumulation of ice. The wet season succeeds," &c.

On the applicability of the Alpaca to our soil and circumstances we quote the following remarks:—

"The hardy nature and contented disposition of the Alpaca, cause it to adapt itself to almost any soil or situation, provided the heat is not oppressive, and the air pure. The best proof of its hardiness is its power to endure cold, damp, hunger, and thirst, vicissitudes to which it is constantly exposed on its native mountains; while its gentle and docile qualities are evinced in its general habits of affection towards its keeper. No animal in the creation is less affected by the changes of climate and food, nor is there any one to be found more easily domiciliated than this. It fares well while feeding below the snowy mantle which envelopes the summits, and for several months in the year clothes the sides of the Andes. It ascends the rugged and rarely trodden mountain path with perfect safety, sometimes climbing the slippery crag in search of food, and at others instinctively seeking it on the heath, or in rocky dells shattered by the wintry storm; at the same time that, when descending, it habituates itself to the wet and dreary ranges on the lowlands, so long as it is not exposed to the intense rays of the sun.

"Many of our northern hills would try the constitution of any sheep, and yet there the weather is never so inclement or so variable as on the Cordilleras of Peru. With so many advantages, why then shall not the Alpaca have an opportunity of competing with the black-faced sheep, the only breed that can exist in those wild and inhospitable lands! Of the two, the stranger would fare best on scanty and scattered food, at the same time affording to the owner a far better remuneration."

The Alpaca wool is at present used largely in British manufactures. Mr. Walton estimates the quantity hitherto consumed since its introduction in 1832 at 12,000,000 lbs. The price of it varies from 1*s.* 8*d.* to 2*s.* 6*d.* per lb., and the average weight of the fleece may be put at 10 lbs. Were the animal fairly naturalised on some of our bleakest hill districts, such land would soon increase in value from the increased worth of its annual produce in Alpaca wool. And it appears from the experience of several gentlemen who have small flocks, that, when its habits shall be thoroughly understood, little difficulty will be experienced in doing so. The following is a statement by Mr. Stirling, of Craigbarnet Place, Lennoxtown, Glasgow—a gentleman better qualified to speak on the subject than any one we could name:—

"I can have no doubt that, when the subject is better understood, the animal itself better known, and a more expeditious method contrived to bring them to Britain, we shall have thousands of them. When known, their docility, their temperate habits, their hardiness, and, I may add, their easy keep, will ere long bring them into general notice. I can answer, without the fear of being contradicted, that they will thrive and breed in Scotland, equal, if not superior to our native blackfaced sheep."

To those who would laugh at the idea of bringing over here, and domesticating on our hills, a Peruvian camel or sheep—for the Alpaca has properties in common with both—we would point to Australia as a country which not many years ago possessed no quadruped but the kangaroo, and yet, notwithstanding its many peculiarities of climate, is now thickly peopled with our sheep and oxen. But the question must not be left to generalities of this kind—the experience of a few short years on the larger scale, which extended importations will enable, will determine it satisfactorily; and if, as in all probability will be the case, the Alpaca should become one of our domestic animals, the best thanks of the country will be due to Mr. Walton for the persevering energy with which he has pressed the subject on public attention. His book is an exceedingly interesting and neatly got up little volume, and will, we doubt not, prove a useful publication.

Miscellaneous.

Extraordinary Produce.—A correspondent says—In the course of last week, as I was taking in some Peas for seed, curiosity induced me to count the number produced from several Peas separately; and among others it gives you the following as a sample:—I found one Pea had produced 94 pods, containing altogether 544 Peas; another 99 pods, containing 868 Peas; a third had produced 102 pods, containing 418 Peas; and a fifth had produced 105 pods, containing altogether 432 Peas. The lengths of the haulm, measured from the ground upwards, are as follow—first, 2 ft. 2 in.; second, 2 ft. 10 in.; third, 2 ft. 6 in.; and fourth, 3 ft.—*Gloucester Journal.*

Notices to Correspondents.

Books.—*Tyro.*—There are many good ones. De La Beche's "Manual;" Lyell's "Elements;" Phillip's "Guide," and his "Treatise" in Lardner's Cyclopædia; Tennent's "Practical Geology and Mineralogy." We have been informed that Prof. Johnston recommends the last to his class.

Bone-dust.—*Querist.*—Apply 3 qrs. of ordinary bone-dust, broadcast, per acre, on your pasture-land, now. We do not know how to destroy wireworms. Work your land thoroughly; lay it well open to the frost; and in your spring cultivation, use Crosskill's clod-crusher, or some equally efficient presser. Perhaps that may help you. See Mr. Childs's Paper on the wireworm, in the English Agricultural Society's Journal.

Dibbling Wheat.—*Constant Reader.*—If you intend to adopt this system on the large scale, use Newberry's dibbling-machine. The seed you will save by its use on 100 acres will pay for it the first year. But if your object is a merely experimental one, a simple dibble used in some places will answer your purpose; it consists of an inverted T with pendant dibbles about 2 inches long at intervals of 8 inches. This makes, perhaps, six holes at each blow, in each of which two grains should be placed—one to grow and one for the birds, if they choose to have it. If you will forward your address, we will publish the facts you state. To decompose common salt, shake caustic lime with a saturated brine, and leave it spread out for a week. The carbonate of lime which is at first formed, decomposes the muriate of soda. Carbonate of soda and muriate of lime—an extremely deliquescent salt—being the resultant compounds.

Distemper.—*T. D.*—Pleuro-Pneumonia only attacks horned cattle. Your dogs have probably got the distemper.—*W. C. S.*

Drainage.—*T. T.*—Many thanks: your views are, we believe, quite correct, and we shall give them prominence as soon as possible.

Draining.—*D. E. F.*—Many thanks for your offer, which we gladly accept.

Flax Dodder.—*B. B. H.*—You must cut it out of your Clovers, gather it in a heap carefully, and burn it. We shall, probably, publish next week for our agricultural readers, the substance of communications on this subject, in the *Gardeners' Chronicle* last year.

Indices of Well-drained Land.—*Querist.*—Land may be well drained though it dries patchy in spring; this may be owing to a variability in the composition of the soil, or to the former existence of occasional peat deposits in the field from stagnant water; it may be well drained, though after heavy rains you find at the lower ends of the furrows the sands and silt washed down and deposited, evidencing a flow of water over the surface; this will often occur after showers on land which is thoroughly dry, either naturally or artificially; it may be drained sufficiently, though water should stand twelve hours after rain in the foot-marks of horses; in ordinary clay soils, the least puddling or breaking of the surface will cause the retention of water on the surface, even at the very edge of a ditch; and land may be sufficiently drained though even twelve months after the completion of the operation, Rushes and Sedges be found in the Grass: their destruction by drainage is a work of years, not of months. But we doubt that it cannot be considered sufficiently drained if a hole 2 ft. deep near drains 30 inches deep retain the water for many days after rain. You must, if this be the case, adopt some measure in dry weather for loosening the subsoil—by subsoil ploughing, for instance. On land such as you describe, 6 yards is a sufficient interval between drains 30 inches deep, to effect its drainage, *i. e.* provided you adopt all possible means of loosening the subsoil after the drains have been some time in action.

Kelp and Guano.—*Subscriber.*—The addition of finely powdered kelp to guano would be advantageous, provided no caustic alkali existed in it. Mix equal quantities. The best mode of using graves for Potatoes or Turnips, though we never before heard of such an application, is, probably, to let it ferment together in a heap covered by fresh mould, and apply probably 4 or 5 cwt. per acre in the drills.

Mangold Wurzel.—*Subscriber.*—We think that the food for cattle afforded by the under leaves of this plant can rarely be worth sufficient to balance the injury done to the plants by taking them off.

Pipe Drain-tiles.—*J. B.*—The publication of the information you require would subject us to advertisement duty. We cannot recommend tradesmen. Mr. Fetherige said at Durham the other day, that you could make them on your own land for 15*s.* a thousand. You had better apply to him about it.

Preparation for Grass.—*Admirer.*—Do not be afraid of spoiling your Grass by tearing it to pieces. A strong harrow will not be sufficiently efficient—you had better use a scarifier and work it to and fro thoroughly, then sow your seeds, and roll with a heavy roller. Do it in wet weather if possible. Much the best plan is to break up your land if it be foul; but this you say you cannot do. Lawson recommends for dry gravelly situations which resist a sward from all ordinary means, Agrostis vulgaris 6 lbs., Festuca rubra 3 lbs., and Poa pratensis 6 lbs. per acre.

Report of Discussion on Potato Failure.—*W. E.*—Thank you: you will see that you have been anticipated.

Tanks, &c.—*A Subscriber.*—Make them circular, basin-shaped at bottom, and cover them over with a flat dome. A depth of 8 ft. and width of 12 will be a convenient size for a stable of 6 or 8 horses. The liquid should have sulphuric acid or sulphate of iron added to it occasionally; and may be removed by a pump and spread directly on the land, or indirectly by making dung heaps. We know of clay lands on which farmers use Cone Wheat only, and on comparatively light soils Red-straw Lammas is used. From experience on both clay and sand we can recommend the varieties advertised in our columns by Mr. Morton.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Sept. 2.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s	0d	to 3s	0	Best Downs & Half-breds	3s	10 to 4s 0
Best Short Horns	3	6	3	10	Best, Long-wools	3	6 3 10
Second quality Beasts	3	0	3	2	Ewes and second quality	3	0 3 4
Calves	3	4	4	0	Lambs	3	8 4 4
Pigs	3	4	4	0			

Beasts, 2811; Sheep and Lambs, 20,240; Calves, 118; Pigs, 200.

We have a large increase in the supply of Beasts to-day, occasioned, in some measure, by several of the freshest Beasts being draughted from the droves intended for Barnet Fair and put into this market; we have not, however, too many of the best qualities in other; still, the prices are lower; nothing can be said to make more than 4*s* per 8 lbs—indeed, only the choicest realise that sum; a very great many remain unsold; 3*s* 10*d* per 8 lbs is also an extreme price for short horns. Our supply of Sheep and Lambs is nearly as large, and the trade worse, especially for big Sheep, owing to the hot weather, and the lower and middling quality are very unsaleable; only the best quality of moderate size maintain their price; these are still worth 4*s* 4*d* per 8 lbs. Veal is lower, and a very heavy trade. Pork-trade is also rather worse, owing to the hot weather.

Friday, Sept. 6.

There is scarcely anything doing in the Beast-market to-day, although the supply of fresh meat is not very large; what are sold make fully 2*s* per 8 lbs less than Monday—Scots, &c., at one time 3*s* 10*d*, and Short-horns, at 4*s* per 8 lbs. The very hot weather during the week has produced a great deal of meat, and prevented the Butchers killing what they have on hand, consequently there is scarcely any demand to-day for either Beasts or Sheep. The best Downs cannot be quoted at more than 4*s* 10*d*, and Long-wools 4*s* 2*d* per 8 lbs. Veal trade is rather improved—a fine Calf is worth 5*s* per 8 lbs. Pork is very heavy.

Beasts, 653; Sheep and Lambs, 2110; Calves, 209; Pigs, 230.

HOPS, Friday, Sept. 6.

Our Market remains firm, and the duty from 180,000*l.* to 220,000*l.* A few more pockets of the new crop have arrived, but being so very inferior, we can as yet form no opinion as to what the quality of the growth may be when it arrives at maturity.

Farebrother & Ellis, Hop-Factors.

COVENT GARDEN, Sept. 7.—Most articles have been abundantly supplied during the week. The demand for some things has, however, by no means equalled the supply. Pine Apples are good and plentiful, as are also Grapes. The supply of Greengage and Orleans Plums is a little diminished, but other kinds are sufficient for the demand. Peaches and Nectarines of good quality are abundant; Apricots are becoming scarce. A few good samples of Morello Cherries are in the market, but there is little demand for them. Apples of many varieties are plentiful. Among Pears are fine specimens of Williams's Bon Chretien. The supply of Filberts is increasing. Of Melons, three is sufficient for the demand, and Cucumbers are good and plentiful. Tomatoes are somewhat reduced in price. Among Vegetables, Cauliflowers have not altered in price since our last Report; Broccoli is becoming more abundant, and Cabbages of excellent quality are sufficient for the demand. Carrots and Turnips are good and plentiful. Owing to the favourable weather that we have had, Celery is unusually good in quality; it is quite clean, and free from rot. Endive, Lettuces, and other kinds of Salading are good and plentiful. Cut Flowers chiefly consist of Gladiolus psittacinus, Gardenia radicans, Combretum purpureum, Fuchsias, Pelargoniums, Lobelias, Heaths, Camellias, Verbenas, Roses, Carnations, and Picotees.

FRUIT.

Pine Apple, per lb., 3*s* to 6*s*		Morello Cherries, per half-sv., 1*s* 6*d* to 2*s* 6*d*	
Grapes, Hothouse, p. lb., 1*s* to 3*s* 6*d*		Currants, per half-sieve, 2*s* 6*d* to 3*s* 6*d*	
— Almeria, per lb., 1*s* to 2*s*		Filberts, per 100 lbs., 30*s* to 70*s*	
Melons, each, 1*s* to 3*s*		Oranges, per dozen, 1*s* to 2*s*	
Peaches, per dozen, 1*s* to 6*s*		— per 100, 6*s* to 10*s*	
Nectarines, per doz., 1*s* to 4*s*		— bitter, per 100, 10*s* to 15*s*	
Apricots, per doz., 2*s* to 3*s*		Lemons, per dozen, 1*s* to 2*s*	
Plums, per half-sieve, 2*s* 6*d* to 3*s*		— per 100, 8*s* to 16*s*	
— Orleans, per half-sv., 1*s* to 2*s*		Almonds, per peck, 4*s*	
— Green Gages, 2*s* to 3*s*		Sweet Almonds, per lb., 2*s* 6*d*	
Figs, per doz., 2*s* to 4*s*		Nuts, Barcelona, 12*s*	
Apples, Dess., per bush., 2*s* 6*d* to 4*s*		— Brazil, 16*s*	
— Kitchen, 2*s* to 3*s*		— Cob, 14*s*	
Pears, Dess., per half-sv., 2*s* to 4*s*			

VEGETABLES.

Cabbages, per dozen, 6*d* to 1*s* 6*d*		Leeks, per bunch, 2*d* to 4*d*	
Cauliflowers, per doz., 2*s* to 3*s*		Onions, per bunch, 2*d* to 4*d*	
Broccoli, per bundle, 6*d* to 1*s*		— large, per bushel, 3*s* to 4*s*	
Sprouts, per half-sieve, 6*d* to 9*d*		Shallots, per lb., 4*d* to 6*d*	
Sorrel, per half-sieve, 6*d* to 9*d*		Cucumbers, per half-sv., 3*s* to 4*s* 6*d*	
Artichokes, per doz., 1*s* to 2*s*		Capsicums, Pkts, per 100, 4*s* to 8*s*	
French Beans, p. half-sv., 1*s* to 2*s*		Tomatoes, per 100, 1*s* to 2*s*	
Potatoes, per cwt., 2*s* to 3*s*		Radishes, per dozen, 2*d* to 3*d*	
Turnips, per doz. bch., 1*s* 6*d* to 2*s*		Lettuces, per score, 2*d* to 3*d*	
Peas, per bushel sieve, 3*s* 6*d* to 4*s*		Celery, per bundle, 6*d* to 1*s* 6*d*	
Red Beet, per doz., 2*d* to 1*s* 6*d*		Celery, White, per bunch, 6*d* to 1*s* 6*d*	
Carrots, per doz. bchs., 2*s* to 3*s*		— Red, per bunch, 1*s* to 1*s* 6*d*	
Basil, per bunch, 2*d* to 3*d*		Endive, per score, 1*s* to 1*s* 6*d*	
Horse Radish, per bundle, 4*s* to 7*s*		Mushrooms, per pottle, 1*s* 6*d* to 2*s* 6*d*	
Savory, per bunch, 2*d* to 3*d*		Small Salads, per punnet, 2*d* to 3*d*	
Cucumbers, Frame, each, 6*d* to 9*d*		Watercress, p. 12 sm. bun., 2*d* to 3*d*	
— Ridge, dozen, 2*s* to 3*s* 6*d*		Parsley, per bunch, 2*d* to 3*d*	
Vegetable Marrow, per doz., 6*d* to 1*s*		Garlic, per bunch, 2*d* to 3*d*	
Spinach, per sieve, 1*s* 6*d* to 2*s*		Mint, per bunch, 2*d* to 3*d*	
Leeks, per bun., 2*d* to 3*d*		Marjoram, per bunch, 2*d* to 3*d*	
Chills, per 100, 2*d* to 1*s* 6*d*		Chervil, per punnet, 2*d* to 3*d*	

MARK-LANE, Monday, Sept. 9.

The accounts from all parts of the Kingdom this morning represent the weather during the past week as having been remarkably fine for the harvest, which is progressing rapidly. This morning the supply of English Wheat was moderate, the quality and condition generally bad, and sales could only be effected at a decline of 2*s.* to 4*s.* per qr. The demand for Foreign was very limited, and we reduce our quotations 1*s.* per qr.—We had a few samples of new Barley at Market, the quality was various, and the value must be noted 26*s.* to 28*s.* per qr.; one very superior parcel from Kent obtained 40*s.* The sale of Foreign was not large, but its late value is supported.—Beans, as also Grey and Maple Peas, are 1*s.* dearer; White are little inquired after.—Oats are in good request, and in some instances a trifling advance is obtained.—We reduce our quotations of the best Mustard 1*s.* per bushel; inferior and damp samples are very unsaleable at a greater decline.

Friday, Sept. 6.

The arrivals of all Corn since Monday have been moderate, and the value of English Wheat sometimes to have a downward tendency. The attendance at Market being very small, scarcely any business in Foreign has been transacted, and prices must be considered nominally unaltered.—Barley is a limited sale at late prices.—Beans and Peas remain as on Monday.—The Oat-trade is heavy, and barely supports our late rates.

James Penney, Wool Broker.

TO GARDENERS, NURSERYMEN, AND OTHERS.

TO BE LET, with immediate possession, within 20 miles of London, a small NURSERY, and PUBLIC-HOUSE doing a good business. The Nursery is well stocked with choicest American Shrubs, Fruit, and other Trees; is situated within a few minutes' walk of a railway station. Every particular can be procured by application to Mr. KENNAN, 4, Great Russell-street, Covent Garden; and Mr. NEAL, Nurseryman, Wandsworth Common. No person without capital need apply.

NURSERY TO BE LET.

TO BE LET, with immediate possession, an Excellent COTTAGE and NURSERY GROUNDS, containing about 8 acres well stocked with a Miscellaneous Collection of Standard and other Rose-trees, Evergreens, &c. The above Stock to be purchased at a fair valuation. It is situated in the vicinity of Croydon, 9 miles from the Bridges, and the soil is extremely well adapted to the growth of all kinds of Nursery Stock. Application to be made to Mr. BARRY, Bedford Nursery, Hampstead road; and to Mr. WILLIS, Rutland, New-road, Croydon, near the Railway-station.

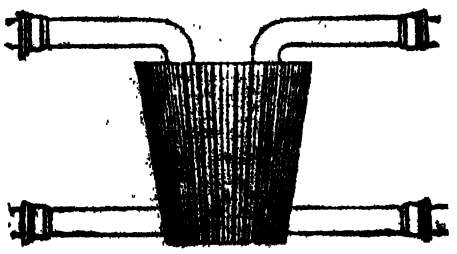
VERY ELIGIBLE FARM.

TO BE LET on LEASE, from Michaelmas next, Forest Lodge (otherwise Llowood), six miles from Brecon, and 16 from Merthyr; containing 700 Acres of Land of the best quality, and in excellent condition. It has a Threshing machine and a Corn and Bone-mill, all worked by water; extensive Barns and Cattle-sheds, a very large Piggery, a Steaming-house, Liquid Manure Tank, and all requisites for the scientific cultivation of the Farm. An excellent Sheep-walk of 700 acres can be attached, if desired. The whole is well situated as to roads.—Apply to Mr. DRAYCOTT, Glanusk, Lenny Bridge, Brecon; or to Mr. LAWES, Basset Down House, Swindon.

FARMS.

TO BE LET, together or separate, at Michaelmas, next, two advantageous FARMS of 800 acres (more or less) of Grass and Arable Land, with a Sheep Walk of 150 acres. For further particulars, inquire of Mr. DANCE, Eynsham, Oxfordshire.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also contract in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 180, FLEET STREET, LONDON.

BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.		Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
in.	£ s.	s.	s. d.	s. d.	s. d.		
10	1 5	20	7 6	6 6	2 6	30 feet.	12 to 20
Ribbed Boiler.							
10	2 2	20	12 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12	2 15	30	12 6	7 6	2 6	80 to 125 feet.	40 to 65
14	3 10	30	17 6	9 6	4 0	150 to 250 feet.	65 to 100
18	5 5	42	25 0	8 6	5 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24	8 15	50	35 0	8 6	7 6	600 to 800 feet.	

If 3 inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

CONICAL BOILERS.—The Boilers invented by JOHN LOUDON, Esq., are made of several sizes, and may be obtained of JOHN SEWARD, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollinson's, Tooting; Foster's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's Park.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that their Manufactory in New Park st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

GYPSUM, &c.—Pure Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.; also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.

Synopsis of Prices, and mode of use, on application.

MARK FOTHERGILL, 40, Upper Thames-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Sept. 7, 1844:—

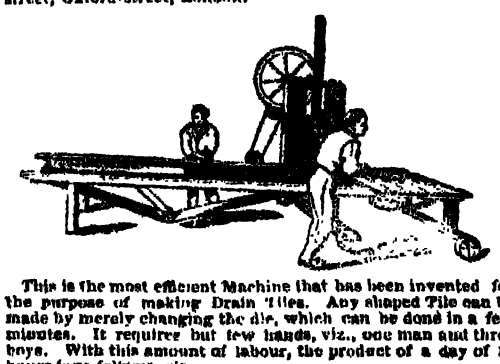
GIBBS, BRIGHT, & CO., LIVERPOOL AND BRISTOL.
47, Lime-street, Sept. 7, 1844.

TO FLORISTS AND ADMIRERS OF FLOWERS.



BRAIN'S CONCENTRATED LIQUID GUANO, for the Garden, Shrubbery, Hothouse, and Conservatory.

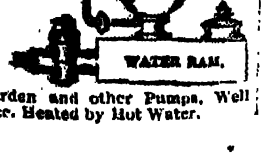
This preparation is peculiarly adapted for the development of Flowers, furnishing them with the materials (in a soluble form) out of which they weave their delicate tissues and elaborate their beauteous colouring. It has no unpleasant smell, is easily applied, and thus recommends itself, either for the Garden or Drawing room.—Price 1s. 6d. per quart Bottle, and may be had of Wm. JACKSON, late Geo. Butler, 93, Cheapside, corner of King-street, and most respectable Druggists and Seedsmen, with full directions for use inclosed.—Works, Thomas st., Stamford-st., Blackfriars rd.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5A, Hawley-road, Kentish Town.

HATCHER'S BENNENDEN TILE-MACHINE, Manufactured and Sold only by COTTAM and HALDEN, Engineers, Agricultural Implement Makers, &c., 2, Winsley-street, Oxford-street, London.

This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With this amount of labour, the product of a day of 10 hours is as follows, viz.:—



1 inch diameter of Tile, 11,800	1½ inches diameter of Tile, 5,600
1¼ ,, ,, ,, 8,000	2 ,, ,, ,, 3,200

The Machine is movable down the drying-sheds, so that it requires no extra boys to carry the Tiles, nor are shelves required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Cranbrook, Kent. No charge made for Patent rights or Licence. The purchase of the Machine includes free use of it.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps. Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs } Colonies
Oil-Cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch Street, London.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade.

THOS. J. CRAMPTON, 8, Ingram-court, Fenchurch-st., London.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, ARCHITECTS, &c.

MCKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, in agricultural districts, many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 8d. each (being less than 9s. 6d. per square of 100 feet), with printed directions for applying them.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Gruneber & Co., 11, Manesty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Rilson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitt; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitchaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKIBBIN'S improved SHEATHING, BOILER, RAILWAY, and other FELT.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam ship, June 6, 1844.*—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup: giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

SILVER PLATED DISH COVERS.—A. B. SAVORY and SONS, Manufacturing Silversmiths, 14, Cornhill, opposite the Bank of England, submit for choice in their Plate rooms many patterns of SILVER PLATED DISH COVERS, of Sheffield Manufacture, from 15 to 20 guineas the set, viz.:—

Double Dome Pattern.	Size.	£	s.	d.	*The Melon Pattern.*	Size.	£	s.	d.
1 Pltd Dish-cover,	20 in.	5	15	0	1 Pltd Dish-cover,	20 in.	5	17	0
1 ,, Dish-cover,	18 in.	4	7	6	1 ,, Dish-cover,	16 in.	4	14	6
2 ,, Dish-covers,	14 in.	5	12	0	2 ,, Dish-covers,	14 in.	6	0	0
Per set .		£13	15	0	Per set .		£16	17	6

The above have silver handles and mountings, and silver shields for engraving the crest or coat of arms. A price current, illustrated by drawings, and containing every information relative to the purchase of silver or Sheffield plate, may be had on application, or will be sent into the country, free of postage, in answer to a paid letter.

EXTIRPATION of all kinds of VERMIN.—Office, 69, King William-street, city, London.—Mr. J. A. MEYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Dragoon Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Gaol, Quays and warehouses in Lower Thames-street, the property of Joseph Barker, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poisonous or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., and 40s. each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, decks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

LITERARY LEAVES; or, Prose and Verse. By DAVID LESTER RICHARDSON. 2 vols 8vo, Second Edition, price 12s.

"We strongly recommend this elegant and entertaining volume. We can easily imagine these Irish writings as stories, sometimes from time to time in the Indian journals, must have pleased the English residents, since even here, in the midst of [illegible] new books, we can [illegible] with [illegible] Idlers.

"His poetry derives, from his undisguised attachment to Nature, a very touching beauty. Most persons who have been long absent from the place of their birth know how delicious is the feeling with which it is approached Mr. Richardson describes this feeling with exquisite truth and tenderness . . . Whatever forms of Nature challenge his preference, he views them all with a poetical eye, and paints them in his verses with vividness and fidelity We should be glad to see the poetry of these volumes detached from the prose, and sent into the world alone It has sufficient character in it to depend on its own vitality; and we venture to predict that it will live."—*Sunday Times*

"The essays afford some exquisite reading. We can with perfect confidence refer every man of literary taste to these volumes, which we consider an elegant and valuable contribution to the literature of our country"—*Inverness News*

"The poems are largely impregnated with Nature's best and holiest feelings They are utterances of the writer's own heart, and they reach the hearts of his readers They leave an impression which will not be easily or speedily effaced. The diction is in keeping with the sentiments; it is at once accurate and graceful The same observation applies to the author's prose writings"—*Observer*

SMITH, ELDER, AND Co, Cornhill, London

Just published, the Thirteenth Edition, price 1s 6d, free by post, 1s 6d,

THE SILENT FRIEND ON NERVOUS DEBILITY, CONSTITUTIONAL WEAKNESS, &c By R and L Perry and Co, Surgeons, London Published by the Authors, and sold at their residence; also by Strange, 21 Paternoster row; Noble, 109, Chancery-lane, Crooker, 1 Milford lane, Strand; Ward, 104, Strand (opposite Exeter Hall) Gordon 146, Leadenhall st.; Purkiss, Compton-st, Soho; Wilson, 338, Oxford st. ADVERTISEMENTS IN THE MONTHLY JOURNAL OF MEDICAL SCIENCE, Edited by Dr Conquest. Few Periodicals present such advantages to the Advertisers of Medical and Scientific Publications, Works in General Literature, Medical Practices, Chemical Products, Pharmaceutical Preparations, the Prospectuses of Life Insurance Societies, &c The circulation is large, and has from its commencement gone on steadily increasing in Great Britain, Ireland, India, America, and the Continent of Europe It is taken in by many General News rooms, by almost all of the Reading Clubs and Medical Societies in Town, and by a very large proportion of Country Practitioners, in England, Scotland, and Ireland, to whom, from its cheapness and comprehensive character, it is specially adapted. Advertisements inserted in this Journal must be seen by many thousands of the most select class of readers.

*** For the SCALE OF CHARGES, and all other particulars, reference may be made to Mr Churchill, Princes-street, Soho, London, Messrs Macnachtan, Stewart, and Co, South bridge, Mr Jack, Nunky street, Messrs Harthill and Son, Waterloo place, and Mr. Seton, Head of the Mound, Edinburgh; Messrs Fannin and Co, Dublin, most News Agents in Great Britain; and Messrs Fortin, Masson, et Cie Paris

"This is the best book on nervousness."—*Professor Savage.*

SIMPKIN and Co, Stationers court, and all Booksellers.

KNIGHT'S WEEKLY VOLUME FOR ALL READERS—PRICE ONE SHILLING

The publication of this series commenced on Saturday the 29th of June, and will be continued every succeeding Saturday The following Works will appear in the course of September.

Sept 7th BIRD ARCHITECTURE By James Rennie,

14th THE ENGLISHWOMAN IN EGYPT. By Mrs. Poole. Vol. II completing the work.

21st THE CHINESE By J. F Davis, Esq, Governor of Hong Kong Vol III completing the work.

28th FAIRFAX'S TRANSLATION OF TASSO'S JERUSALEM DELIVERED With Lives of Tasso and Fairfax, Vol. II. completing the work

London: CHARLES KNIGHT & Co, 22, Ludgate-street.

THE HORTICULTURAL MAGAZINE.—On the 1st of October will be published, price One Shilling, the INTRODUCTORY NUMBER of this new periodical.—Orders received by all booksellers It is earnestly requested that members of Horticultural Societies, and all persons who take an interest in a garden, will forward to the Editor the results of their experiments and practice.—Office, 162, Strand, London, where advertisements and communications for the Editor may be forwarded.

To the Nobility and Gentlemen of the United Kingdom of Great Britain and Ireland, and to their Gardeners, Land Stewards, Foresters, and Farm Bailiffs.

THE UNITED GARDENERS' and STEWARDS' JOURNAL; or, The NOBLEMAN'S and GENTLEMAN'S CULTIVATOR of the GARDEN, the FARM, and the FOREST. A Weekly Journal of the Contributions of a combination of the Cultivators of the Earth and her Products, conjointly with the ordinary News of the Day, will be published on SATURDAY, the 4th of JANUARY, 1849, providing a sufficient number of Subscribers come forward to enable the Society to do so: the proceeds of which are intended to form a Fund for the Relief of Aged and Indigent Gardeners, Land Stewards, Foresters, and Farm Bailiffs, and for their Widows and Orphans.

The Gentlemen's Gardeners have long complained that, while every other profession has its "club" for the relief of their unfortunate brethren, they have nothing of the kind, which in all probability has hitherto arisen from their isolated situations

The Gentlemen's Gardeners' Benevolent Institution, now formed of some of the leading Gentlemen and Stewards in that neighbourhood, is about forming Sub Committees of the principal gardeners and stewards in every county and division of counties in the kingdom, to assist in the management of the Charity.

We have been advised to write an appeal to the feelings of the Nobility and Country in behalf of our Charitable Institution; but as such circulars are every-day performances, which have been becoming worse the longer for ages, we think it by far the most original course to adopt such measures as are sure to meet their approbation, and secure their patronage and esteem.

To Advertisers, the Journal will offer the lowest possible charges for everything connected with Horticulture, Agriculture, Floriculture, and Arboriculture, and all new inventions either of Manure or Implements.

The plan hitherto adopted in this business has been, that every Member has paid a Quarter in advance (6s. 6d.), but now arrangements are so far advanced with our printer, that persons who scruple to do so, until they have received the first Number of the Journal, will oblige by forwarding their addresses.

All letters and parcels for the Journal to be addressed to the care of our Printers, WERTHEIM BRAYMAN & Co, Peterborough Court Fleet street

Price 7s, Illustrated with Wood-cuts of Birds, Cages, &c.

NATURAL HISTORY of CAGE BIRDS; their Management, Habits, Food, Diseases, Treatment, Breeding, and the Methods of Catching them. By J. M. BECHSTEIN, M.D.

"It will be welcome to every gentleman's library or drawing-room table. It is superbly got up, with an immense number of vignettes, and in fact rivals the beauty of the Annuals."—*Weekly Chronicle.*

"A very delightful book of its kind. . . . . It seems to us an indispensable book for the bird-fancier."—*Spectator.*

London: W. S. Orr and Co.; and W. R. CHAMBERS, Edinburgh.

TO SPORTSMEN, TOURISTS, &c

BERDOE'S SUPERIOR WATERPROOF FROCKS, SHOOTING JACKETS, GARMENTS for the SEA SIDE, &c.—An extensive variety of the above, in new and greatly improved materials always ready, guaranteed to exclude any rain whatever, and confidently recommended to those who require a respectable appearance, or wish to avoid the disappointment and vexatious annoyance upon purchasing articles made by shopkeepers, and sold by parties not Tailors

FIRST-RATE CLOTHING of every description, upon the lowest terms possible, consistent with extra economy, and ultimate satisfaction.—W. BERDOE, Tailor, Waterproofer, &c., 69, Chancery lane.

EXTIRPATION of the WEEDY BUG, THRIPS, &c.—These pests to Gardens can be readily and effectually extirpated without injury to the most delicate plants, by HERSMAN'S VEGETABLE DILUTUM, sold in bottles at 6s, 10s, and 20s each, free of carriage to all parts of Great Britain.—Address, with a remittance, either to SAMUEL HERSMAN, Romsey, Hants, or Messrs. MANWOOD and MANLY, Nurserymen, &c, Hackney, who are the sole London Agents

SIX POUNDS OF TEA, whether Black or Green, for 17s; and small bright Gunpowder, in 12 lb boxes, at 4s 6d per lb. East India Tea Company's Offices, 9, Great St. Helen's Churchyard, Bishopsgate-street.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c, Manufactured by BOULTON and WATTS, LAMBETH POTTERY, High-street, Lambeth, London.

D and W, from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom One, two, and three-light Cucumber and Melon Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two light Boxes and Lights complete, from 3l. 8s. Garden Lights made and glazed from 1s per foot, at JAS. WATES' Sash Manufactory, Claremont-place, Old Kent-road *** Reference given

ROWLAND'S ODONTO, OR PEARL DENTIFRICE, patronised by "HER MAJESTY," H R H Prince ALBERT, the Royal Family, and the several Courts of Europe. A FRAGRANT WHITE POWDER, prepared from Oriental Herbs of inestimable virtue, for strengthening, preserving, and cleansing the teeth. It eradicates the fetitious formation of tartar, and by the removal of that extraneous substance lends a salutary growth and freshness to the gums. It removes from the surface of the teeth the spots of incipient decay, polishes and preserves the enamel, substituting for discolour and the aspect of impurity, the most pure and pearl like whiteness; while, from its antiseptic and disinfecting qualities, it gives sweetness and perfume to the breath, bestowing at once cleanliness, and the appearance and reality of health. Price 2s. 9d. per box, duty included.

CAUTION.—To protect the public from fraud, the Hon. Commissioners of Her Majesty's Stamps have authorised the Proprietors' Signature to be engraved on the Government Stamp thus,—A. ROWLAND and Son, 20, Hatton Garden, which is affixed to each Box Ask for ROWLAND'S ODONTO. Sold by them, and by Perfumers and Chemists.

*** All others are SPURIOUS IMITATIONS.

Printed by WILLIAM BRADBURY, of No. 6, York place, Stoke Newington and FREDERICK MULLETT EVANS, of No. 2, Church row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-street, in the parish of St. Mary Woolnoth, in the City of London; and published by them at the Office, No. 5, Clarke-street, in the parish of St. Paul's, Covent-Garden, in the said county, where all Advertisements and Communications are to be delivered to the Editor.—Saturday, September 7, 1848.

UNIVERSITY COLLEGE, LONDON.—Faculty of Medicine.—Session 1844-45.—The CLASSES will commence on Tuesday, the 1st of October, when Professor COOPER will deliver an INTRODUCTORY LECTURE on the Study of Surgery, at 2 o'clock precisely.

Classes in the order in which Lectures are delivered during the day.

Medicine, Principles and Practice of—Professor Williams, M.D.
Anatomy and Physiology—Professor Sharpey, M.D.
Chemistry—Professor Graham.
Anatomy—Professor Quain.
Comparative Anatomy—Professor Grant, M.D.
Materia Medica and Therapeutics—Professor Thomson, M.D.
Midwifery—Professor Murphy, M.D.
Dental Surgery—Lecturer, Mr. Durancé George.
Surgery—Professor Cooper and Mr. Liston, Professor of Clinical Surgery.
Practical Anatomy.—The pupils will be directed in their studies during several hours daily by Mr. Ellis and Mr. Potter, under the superintendence of Mr. Quain and Dr. Sharpey.

SUMMER TERM.

The following subjects will be taught during the summer term:
Botany—Dr. Lindley.
Midwifery—Dr. Murphy.
Pathological Anatomy—Dr. Walshe.
Comparative Anatomy and Zoology (Elementary Course)—Dr. Grant.
Forensic Medicine—Dr. Thomson.
Practical Chemistry—Mr. Graham.

Hospital Practice daily throughout the year:—
Physicians—Dr. Williams, Dr. Thomson, Dr. Taylor, Dr. Walshe.
Obstetric Physician—Dr. Murphy.
Consulting Surgeon—Mr. Cooper.
Surgeons—Mr. Liston, Mr. Quain.
Assistant Surgeon—Mr. Morton.
Dental Surgeon—Mr. Durancé George.
Medical Clinical Lectures—Dr. Williams and Dr. Thomson, and also by Dr Taylor, Professor of Clinical Medicine, whose special duty it is to train the pupils in the practical study of disease at the bedside during the visits, and also by a series of lessons and examinations on the physical phenomena and diagnosis of disease, to classes consisting of a limited number and meeting at separate hours.
Surgical Clinical Lectures—Mr. Liston, Mr. Quain.
Obstetric Practice under the superintendence of Dr. Murphy.

Prospectuses may be obtained at the office of the College.

Residence of Students.—Several of the Professors, and some of the Masters of the Junior School, receive Students to reside with them; and in the office of the College there is kept a Register of parties unconnected with the College, who receive boarders into their families; among these are several medical gentlemen. The Register will afford information as to terms and other particulars.

The Report of the Distribution of Prizes in the Faculty of Medicine for the past Session, with the Examination Papers, is ready. Former Students of the College may have it forwarded to them on sending their address.

THOMAS GRAHAM, Dean of the Faculty.
CHAS. C. ATKINSON, Secretary to the Council.

August, 1844.

The Lectures to the Classes of the Faculty of Arts commence on the 15th of October.

The Junior School opens on the 24th of September.

LAST FLORAL FETE OF THE SEASON!

ROYAL SURREY ZOOLOGICAL GARDENS, TUESDAY, SEPT. 17th, 1844.—GRAND DAHLIA AND MISCELLANEOUS FLOWER SHOW, for Flowers, Fruit, and Vegetables, combined with the following attractions:—Picturesque Grounds, Superb Menagerie, Gigantic Model of Old London, Blight's Corinthian Brass Band, Modal of Venice, Feeding of the Carnivora, Promenade Concerts, introducing Beethoven's Battle Sinfonia, Spohr's "Consecration of Sounds," &c., and Great Fire of London, allowed to be the grandest Pyrotechnic Display ever witnessed. No Establishment in Europe presents so many, varied, and unique attractions.

Admittance 1s. Open at One. Conflagration at Eight o'clock

NEW CARNATIONS, PICOTEES, AND PINKS.

MESSRS. N. and B. NORMAN'S CATALOGUE of SHOW VARIETIES can be had on prepaid application.—Bull Fields, Woolwich.

THE ROYAL BOTANIC SOCIETY of LONDON, Incorporated in 1839, for the promotion of Botany in all its branches, and for the formation of an extensive Botanical and Ornamental Garden within the immediate vicinity of the Metropolis, will meet for a PROMENADE in their Garden in the Regent's Park every WEDNESDAY in MAY, JUNE, and JULY, 1845 (weather permitting), excepting those Wednesdays selected for the Exhibitions of Plants, Flowers, &c.

J. DE C SOWERBY, Secretary.

ROYAL BOTANIC SOCIETY, REGENT'S PARK.—The following days being the first WEDNESDAYS in MAY, JUNE, and JULY, 1845, are appointed for the EXHIBITIONS of PLANTS, FLOWERS, &c., in the Garden of this Society in the Regent's Park:—

MAY 7th,
JUNE 4th,
JULY 2d.

But should the Ascot Races be fixed for the first week in June, then the June Exhibition to be on Wednesday, the 11th.

J. DE C. SOWERBY, Secretary.

GRAND DAHLIA SHOW, SEPT. 25, Bazaar, Baker-street, Portman-square, London.—Committee:—Messrs. Widnell, Girling, Brown, Atwell and Brown, Keynes, Harrison, Sorrell, Bragg, Stein, Turner, Whale, Sparrey, Hansard, Edwards, Low, Mitchell. Prospectus, of any of the Committee, and at the Bazaar. Entrance, on or before the 20th. Seedlings to come out in the spring will be shown, six blooms each; Seedlings of the present year, one bloom each. A Dinner will take place at half-past three.

EXHIBITION OF LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment FLORIST TO HER MAJESTY, begs to inform the Nobility, Gentry, and Amateurs, that he has above 4000 blossoms of this most beautiful LILY, now in flower, including the rare and splendid variety "Speciosum," which is held in such high estimation by the Japanese. May be viewed every day, Sundays excepted. Admittance, gratis.—Clapham Rise, Sept. 11, 1844.

HURST AND M'MULLEN, 6, Leadenhall-street, beg to inform their Friends that their importations of DUTCH AND CAPE BULBS have just arrived, in very fine condition. Catalogues may be had on application.

"PRINCESS ALICE MAUDE" STRAWBERRY. Plants of this splendid Strawberry, the earliest known, 25s. per 100.
Myatt's British Queen, 6s. per 100.
Myatt's Deptford Pine, 25s. per 100.

PINE-PLANTS.—To be Sold by Auction (if not previously disposed of), at the Gardens, Foxholes, on WEDNESDAY, Sept. 25, at One o'clock, the entire Stock of PINE-PLANTS, consisting of Montserrat, Providence, and two Seedlings named the "Black Prince" and "Prince Alfred," in all 300 Plants. The Seedlings grow to a great size, and are of good flavour. A Pit of these Seedling Pines in fruit may now be seen at Foxholes, near Rochdale, averaging 8 lbs. weight.—Sept. 12.

THE NEW SUPERB SEEDLING PICOTEE, "BURROUGHES'S DUKE OF NEWCASTLE."

YOUELL & CO. have much pleasure in announcing they will send out for the first time the above splendid light-edged purple Picotee, raised by the Rev. J. Burroughes. It is guaranteed to surpass any Purple Picotee that has yet been raised. Without commenting further upon its superiority, Y. and Co. beg to refer to a report in a late No. of the *Gardeners' Chronicle*, as follows:—

"The *Duke of Newcastle* is a flower of first-rate properties; it is a light-edged purple; the petals are large, and of good form and substance; even on the edge; the colour unbroken; the pod good, and with less disposition to bar than is common." It obtained the first prize as the best seedling, at the Norfolk and Norwich Horticultural Exhibition. Price 21s per pair, and will be sent out the latter part of next month. The stock being limited, to prevent disappointment early orders are respectfully requested. Y. & Co. will also be enabled to supply at the same time the following superb Picotees, raised by the same gentleman, all possessing first-rate properties, and having been exhibited and obtained first class prizes at several of the metropolitan Exhibitions of the present year. They are as follows:—

Burroughes's	Mrs. Benyon, Red Picotee	7s. 6d.
,,	Lady Alice Peel, Rose Picotee	7 6
,,	Miss Jane, Purple Picotee	7 6
,,	Miss Bevan, Red Picotee	7 6
,,	Enchantress, Scarlet Picotee	5 0

CARNATIONS AND PICOTEES.

Y. and Co.'s collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit. The plants are remarkably strong and healthy, and will be ready for sending out to any part of the United Kingdom and the Continent the latter part of this month, at the following prices:—

				£	s.	d.
12 pairs extra fine and very superior first-class Show Flowers				2	10	0
25	ditto	ditto	ditto	5	0	0
12	ditto	ditto	Show Flowers	1	10	0
25	ditto	ditto	ditto	3	0	0

The selection being left to Y. and Co.
Great Yarmouth Nursery, Sept. 13, 1844.

RARE AND BEAUTIFUL COLUMBINE, &c.—The Subscribers beg to intimate that they have saved Seeds of a superb variety of Aquilegia glandulosa. This splendid Columbine is a hardy Perennial, and forms one of the most gay border-plants in cultivation; it grows to the height of from 12 to 18 inches, abounding in two-coloured blossoms—blue and white—of the size and shape of the common Passion-flower. Packages of about 150 Seeds are sent free at 1s. per packet, or for stamps of that value. The trade can be well supplied with seedling and transplanted native Scotch Firs and Larches. Choice named Carnations, &c.

JOHN GRIGOR and Co., Nurseries, Forres, N.B.

EARLIEST STRAWBERRY in CULTIVATION.—Strong Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 20s. per 100. As an Early Strawberry, it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the "British Queen," "Deptford Pine," "Prince Albert," and all the leading kinds. To be had of Messrs. WARNER & WARNER, Seedsmen, 28, Cornhill, London.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of those splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs. WARNER & WARNER, Cornhill, London, after the 7th September.

TO CALCEOLARIA GROWERS.

THE present being a good time to sow CALCEOLARIA SEED, the Advertiser begs to offer a few packets of his splendid New Spotted kinds, saved with great care, with printed directions to raise the young plants, at 5s. per packet.—J. STANDISH, Nurseryman, Bagshot.

T. AND J. BACKHOUSE, NURSERY & SEEDSMEN, York, beg to offer to the notice of the Public their following fine SEEDLING PANSIES:—

YORKSHIRE ECLIPSE.—"No. 1 is a large flower, of good form, white ground, blue purple upper petals, and broad margin of the same round the lower petals; the petals meet well above the eye; a good flower." 3s. 6d.

BEAUTY OF HOLDGATE.—"No. 2 is your best flower; the eye large and intensely dark, ground light buff, belting purple, upper petals the same; a brilliant and striking flower." 3s. 6d. (See *Gardeners' Chronicle*, p. 280, for 1844.)

EARL OF ZETLAND is a flower of excellent form, yellow ground, bronzy crimson upper petals, with broad belting of the same round the lower petals, which meets well above the eye; a distinct and very constant show flower. 3s. 6d.

Strong plants are now ready for sending out, postage free when three or more plants are taken. A remittance required from unknown correspondents.

INGA PULCHERRIMA. (Figured in "Paxton's Magazine of Botany" for August, 1844.)—Fine Plants of this extremely elegant and beautiful Exotic, with most of the other new and rare Plants of the season, may be obtained of the undersigned, at the following low prices:—

Inga pulcherrima, 7s. 6d.	Habrothamnus elegans, 18s.
Achimenes picta, 10s. 6d.	Tremandra Hugelii, 10s. 6d. to 21s.
Aeschynanthus Horsfieldii, 7s6d	Veronica speciosa, 8s. to 18s.
Amycla zygomeris, 7s. 6d.	Erica elegans, fine and healthy, 15s., 24s., and 30s. per doz.
Clerodendron splendens, 5s, 10s.6d	Drymonia punctata, 8s. 6d.
,, squamatum, 5s.	Pilox Van Houttei, (flowering plants), 2s.
Rhodia, or Rondeletia longiflora, 18s.	Spirea Reevesiana, 5s.
Epacris campanulata rosea (the finest selected from 1000 seedlings), 7s. 6d.	Viburnum coteaifolium, 3s. 6d.

Also the following, in collections:

100 Cape Ericas of 100 distinct sorts, (including many fine sorts) 5l.	(including Campanulata rosea) 21s.
12 Epacrises of 12 distinct sorts,	12 Azalea indica, of 12 distinct sorts, (including fulgens) 21s.

THOMAS JACKSON, Kingston Nursery, Surrey, Sept. 13.

SPLENDID NEW SEEDLING CINERARIAS.

MICHAEL BREWER, Sen., begs to return his best thanks to his numerous friends who last season favoured him with their orders, and to apprise them that in addition to his own extensive List of varied Self and party-coloured new and truly splendid Seedlings of the present year, he made purchase of every new advertised and well-described kind, which having propagated and seeded to great extent, he is now prepared to execute orders for strong seedling plants, fit for furnishing to the Greenhouse, through the autumn and winter months, a varied, lively, and continuance of elegant bloom, comprising every shade of deep rich purple, dark and light blue, &c., at 9s. per doz., basket, &c. included. Also seed of the same, which he confidently recommends on account of all being grown mixed together. Mixed and collected in packets, 2s. 6d. each.

Letters, inclosing post-office orders or stamps, will be immediately attended to.—Nursery, London-road, Cambridge.

KINGHORN'S SPLENDID CALCEOLARIAS.—In reply to numerous correspondents, WILLIAM MAY begs to intimate that the Calceolarias he advertised are not the same as advertised by another party, but totally and distinctly different. W. M. having had the choice of the whole collection, he selected five of the most distinct and best varieties, which he purposes sending out in March next, that being the best season for receiving Calceolarias.—Hope Nursery, Bexley, Sept. 12.

ROSES.

A. PAUL AND SON, respectfully announce that their Annual Descriptive ROSE CATALOGUE will be ready for circulation in a few days, and may be obtained from the Nurseries post-free, upon application inclosing two postage stamps. Their stock is very large, and having been grown on new ground, the plants are more than usually robust and healthy. All the really valuable new Roses are in their collection.

TO NOBLEMEN and GENTLEMEN PLANTING.—A. PAUL and SON would also call attention to their Fruit and Forest Trees, Ornamental Trees, Shrubs, Evergreens, &c. &c., which are growing on upwards of 25 acres of ground, and are on sale upon the most reasonable terms. The soil is a stiff loam, from which Trees remove in perfect safety, having abundance of fibrous roots, and the earth adhering thereto. The proximity of the Nurseries to the Metropolis, and the advantageous terms of sale, recommend them especially to gentlemen planting.

Nurseries, Cheshunt, Herts, 13 miles from London, near the Waltham Cross Station on the Cambridge Line of the Eastern Counties Railway.

TRUE HIGHLAND PINE.

JAMES GRIGOR, Nurseryman, Norwich, begs to call the attention of the Land Proprietors of England to this very desirable variety of Pinus sylvestris, which has been raised from seeds collected on the mountains of Strathspey, and of which he has strong plants ready to be sent out. For introducing this tree Messrs. Gaicon, of Forres and Elgin, were awarded several premiums by the Highland and Agricultural Society of Scotland; and in that part of the country this Pine is rapidly superseding the common soft-wooded variety. For all economical purposes its chief merit consists in the hardiness and durability of its wood; hence it is much sought after at present for railway sleepers. Pictorially considered, or as a landscape ornament, it rivals even the Cedar of Lebanon. Sir Walter Scott describes it as assuming much of "the bold and undecided figure of the Oak;" and in the last No. of the *Quarterly Review* it is recommended as a fit tree to be planted in churchyards and cemeteries.

Strong plants in pots, such as rabbits and hares will not destroy	. . . . .	6*d.* each.
Ditto, not in pots, 18 inches high	. .	30*s.* per 1000.
Ditto " 15 "	. .	20*s.* "
Ditto " 1 foot high	. .	15*s.* "
Ditto " 2 years old	. .	10*s.* "

J. G. would recommend all who require them to furnish themselves immediately with these Pines, and to plant them forthwith. Spring planting is exceedingly hazardous; and when followed by such a season as was experienced during the commencement of the present summer, the young trees are sure to be killed.

Cedrus Deodara raised in the open ground, being the strongest plants yet offered in England, 10*s.* each. Araucaria imbricata, Pinus excelsa, Laricio, Austriaca, &c. &c. on reasonable terms.

JOHN SLATER, Florist, Cheetham Hill, near Manchester, respectfully calls the attention of the Floricultural Public to his large and select collection of the following Florists' Flowers:—TULIPS, AURICULAS, POLYANTHUSES, CARNATIONS, and PICOTEES; catalogues of which may be had on prepaid application. 12 plants of named Auriculas, of different varieties, for 20*s.*, package included. 20 pairs of Carnations and Picotees, good named varieties, for 20*s.*, package included.

NEW PANSY SEED.

WILLIAM CLARK, 25, Bishopsgate-street-within, London, is now sending out the above from the best flowers grown, in papers of 2*s.* 6*d.* and 5*s.* each. Also J. H. Cox, Esq.'s Superb Picotee Seed, 5*s.* per paper; fine Cineraria, Calceolaria, Polyanthus, and Auricula, 1*s.* per paper—may be had on receipt of a post-office order.

ACHIMENES PICTA.

W. J. EPPS begs to announce that he has the largest stock of this valuable Plant, which he can supply strong Plants of at 5*s.* each, or 2*l.* 2*s.* per dozen. Also the New and Splendid Buddlea Lindleyana, 5*s.*; Drymonia punctata—strong flowering plants, 5*s.*; Aristolochia gigas, 5*s.*; Clerodendrum laevifolium (a distinct and beautiful variety), 5*s.*; Gloxinia Cartonii, 5*s.* to 7*s.* 6*d.*; G. bicolor, 5*s.*; insignis, 5*s.*; G. magnifica, 5*s.* Strong plants of nearly all the new Fuchsias sent out this year, 15*s.* per dozen.

Bower Nursery, Maidstone, Sept. 12, 1844.

CINERARIA "SILVER QUEEN."

A. PAUL AND SON, Nurserymen, &c., Cheshunt, Herts, beg to offer the above novel and beautiful Cineraria, which was exhibited at the Horticultural Society's Rooms, in Regent-street, and awarded a certificate there.

"A singular and handsome seedling Cineraria, showing a disposition to quill, by the purple rays of the flower being drawn together for some distance from their bases, and thus forming a tube having a silvery appearance."—*Gardeners' Chronicle.*

"From Messrs. Paul and Son, of Cheshunt, a Cineraria, doubly quilled, of a lilac or beautiful and singular silvery appearance."—*Gardeners' Gazette.*

Strong Plants now ready, 5*s.* 6*d*, including package, or post free, 6*s.* An order on Waltham Cross post-office expected from unknown correspondents. The usual discount to the Trade when six plants are taken.

DUTCH HYACINTHS.

WARNER AND WARNER, Seedsmen, No. 28, Cornhill, London, respectfully inform the Nobility and Gentry their Dutch Flower-roots have arrived in superior condition, consisting of the choicest and newest varieties. The Bulbs are unusually handsome and large, at moderate prices. Catalogues forwarded by post on application.

CAMELLIA "EMPEROR."

T. DAVIES AND Co. beg to inform their friends and the Public, that they now intend sending out the above magnificent Seedling, raised and flowered by them in 1843, when it was exhibited at the rooms of the Horticultural Society of London, where it was awarded a Prize, and afterwards spoken of by Dr. Lindley, in his Report of their Meeting, in the following terms, in the *Chronicle* of 25th March, 1843:—"Messrs. Davies & Co., exhibited a very handsome Seedling Camellia, raised from the seed of C. colvillii, fertilised with the pollen of C. reticulata. In the foliage it resembles the older sorts, but the flower, which is large and well filled up, partakes of the form and colour of its male parent. A certificate was awarded for it." Price from 3*l.* 3*s.* to 4*l.* 4*s.* Stock positively very limited.

CEREUS GRANDIFLORUS RUBRA. This splendid new variety of Cereus was raised by T. D. & Co. in the manner described by Dr. *Lindley* in the Leading Article of last week's *Chronicle*. The flowers measure 10 inches in diameter, are of a pale-red colour, with a shade of purple in the centre. They expand about 7 o'clock in the evening, and last nearly the whole of the next day, being an advantage over the night-blooming, which generally close early the next morning. Strong plants are now ready for sending out at 10*s.* 6*d.* each. Reference or remittance required from unknown correspondents.—Waverlree Nursery, near Liverpool, 14th Sept., 1844.

MR. LYNE'S NEW SEEDLING GERANIUMS.

WILLIAM E. RENDLE has much pleasure in offering to the Nobility, Amateurs, and Trade the following new varieties of GERANIUMS raised by P. E. Lyne, Esq., the entire stock of which he has succeeded in obtaining.

Lyne's Princess Alice	each	*s.* 1	*d.* 1
Lyne's White Perfection	"	1	1
Lyne's Imogene	"	1	1
Lyne's King of Saxony	"	1	1
Lyne's Redworth	"	1	1
Lyne's Confidence	"	1	1
Lyne's Sappho	"	1	1

The whole set as above for six guineas. The usual discount to the Trade.

"Princess Alice" has received two seedling prizes in London, "White Perfection," first prize at Torquay, and the Gold Medal at Bath. "Imogene" is described in the *Chronicle*, June 24th, 1843. They all possess most desirable properties, and can be highly recommended as being first-rate flowers.

W. E. R. has been induced to offer the above at prices considerably lower than usually obtained for such valuable varieties, in hopes thereby to meet with a more extensive demand. Descriptions can be obtained on application.

Orders will be executed in strict precedence. Plants will be delivered in October next. Reference or remittance required from unknown correspondents. Plants will be added to compensate for carriage.—Union Road Nursery, Plymouth, Sept. 13.

ROSES.

WOODLANDS NURSERY, Stradfield, Near Uckfield, Sussex. WOOD & SON have the honour to announce that they are now issuing GRATIS, on application, their newly-arranged CATALOGUE OF ROSES, containing a full and comprehensive description of all the most popular varieties, in addition to the novelties that have appeared this season.

Catalogues may be had at Edinburgh, of Mr. R. T. M'Intosh, 12, Catherine-street. Woodlands, September 13.

T. AND C. LOCKHART, Seedsmen and Florists, 155, Cheapside, London, beg to announce that their CATALOGUE OF FLOWER-ROOTS for the present season will be forwarded post-free on application.

GERANIUM "CELESTIAL."

CHANDLER AND SONS, Nurserymen, Vauxhall, London, have now ready to send out young plants of their New Geranium "CELESTIAL," which has been so much admired. The flowers being very large, and with a beautiful white throat, it is one of the most conspicuous varieties that has yet been raised. Plants, 10*s.* 6*d.* each.

C. and Sons have also to offer healthy young plants of CAMELLIAS of sorts, with flower-buds, at 30*s.* per dozen; larger plants 42*s.* per dozen; and good plants of the newer sorts 60*s.* per dozen. Also good plants of the best sorts of CHRYSANTHEMUMS, at 12*s.* per dozen; larger plants, 18*s.* per dozen. The package included in the above prices. A remittance or reference for payment in London will be expected from unknown correspondents.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4*s.* per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. Corbett's, late Mr. Barron's, Italian and Foreign Warehouse, 13, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

ARAUCARIA IMBRICATA.

SPLENDID NEW PINUS.—Fine healthy Plants about 9 inches high, can be had at Hurst and M'Mullen's Seed-shop, No. 6, Leadenhall-street, London, at 5*l.* per 100.—September 13.

CAMELLIA JAPONICA.

ROBERT LAWSON, Esq., of Tiverton, intends disposing of his stock of Camellias, which he has collected at much expense, and successfully cultivated for many years. They are in the highest state of health, and most abundantly set with blooming buds. Mr. L. disposes of them solely in consequence of their having become too large for his conservatory. They are as follows:—

				£	*s.*	*d.*
Reticulata,	from 7 to 8 feet in height,	a very fine specimen, quite healthy and green	. . .	10	10	0
Imbricata,	from 7 to 8 feet in height,	do.	.	8	8	0
"	" 5 to 4 "	. . .	.	1	10	0

Insignis	" 6 to 7 "	.	very fine	2	10	0
Eclipse (Press's)	6 to 7 "	. . .	.	2	3	0

The Prices affixed are for the separate plants, of which not less than 3 can be taken together. If the whole are taken in one lot a considerable reduction will be made. Mr. Lawson will be happy to show them, or give any further particulars that may be required.—Tiverton, Sept. 12th, 1844.

HYACINTHS AND OTHER DUTCH BULBS.

CLARKE & CO. beg to intimate to their Friends and the Public, they have just received their annual supply of the above roots, direct from the first rate growers in Haarlem.—Catalogues may be had, post free, which will be found to comprise every novelty of the season. London, 86, Highst., Boro'. Sept. 13,

BRACONDALE HORTICULTURAL ESTABLISHMENT.

JOHN BELL begs to inform his Friends and the Public, he has just received his Importation of DUTCH HYACINTHS AND OTHER BULBS, direct from Haarlem. Catalogues of which may be had at the Nursery, or his Seed Warehouse, 3, Exchange-street, Norwich.

SEEDLING FUCHSIA "NORFOLK HERO."

JAMES BARKWAY respectfully begs to call the attention of Amateurs and others to the above splendid Fuchsia; it has been pronounced by all that have seen it to be the best light one yet out. See Dr. Lindley's opinion in the *Gardeners' Chronicle* July 13th:—"*J. B.*—Your seedling is a finely-formed flower; tube and sepals of the most delicate pink, approaching to white; corolla rose, with a slight tinge of purple; a clear and brilliant flower; the best of its class we have yet seen." Also, August 10th, when sent with five other seedlings,—"No. 3 is the best in form." It obtained a prize at the Norfolk and Norwich Horticultural Show, as a seedling, July 31.

Plants of the above-named are now ready at 7*s.* 6*d.*; strong plants, with three or four side shoots, 10*s.* 6*d.* each, carriage, &c. included, if sent by post or otherwise.

J. B. has been very successful in raising Seedling Calceolarias, of which see Dr. Lindley's opinion June 8th and August 10th, of which price, &c. will be given when ready to send out.—East Dereham, Norfolk.

F. C. BALL, successor to Mr. John Young, Nurseryman, Taunton, begs to offer 20 or more varieties of IXIAS at 4*s.* per dozen. A List of Ixias and other bulbs will be forwarded on application. An allowance to the Trade. Fine Plants of Geneeria zebrina at 1*s.* 6*d.* each.—Sept. 12, 1844.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	Orange Tubs, Flower Boxes, &c.
Garden Edging	

Edward Buck will be happy to answer any inquiries, either personally or by post.

HYACINTHS, IRISES, ANEMONES, &c.

SUTTON AND SONS respectfully recommend the readers of the *Gardeners' Chronicle* to observe their List of Prices, published in the 2nd page of the *Chronicle* for 31st Aug. J. S. and Sons consider their Collections of IRISES, HYACINTHS, and ANEMONES, which they have imported this season, to be fully equal to any in Europe, and the prices will be found remarkably low. Descriptive Catalogues (as recommended by Dr. Lindley in last week's *Chronicle*) may now be had gratis at their Seed-shop, 7 and 8, Market-place, Reading, Berks.—N.B. Parcels delivered free to the Railway and Packet Offices in London, or any Station of the Great Western Railway within 60 miles of London.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND-MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. In Tin, 1*l.* 10*s.* each; or with Copper Box and Tube, 1*l.* 15*s.* each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. Cottam and Hallen, 2, Winsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers in the United Kingdom; or from the Inventor, by letter, to his address, inclosing a Post-office order for the amount.—Richard Smith, Upper Hall, near Droitwich, Worcestershire.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon-Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Boxes and Lights complete, from 1*l.* 8*s.* Garden-Lights made and glazed from 1*s.* per foot, at Jas. Watts' Sash Manufactory, Claremont-place, Old Kent-road. **** Reference given.

TO GENTLEMEN, BUILDERS, NURSERYMEN, & OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed to Sell by Public Auction (under a bill of sale), on the premises, Sussex Nursery, Loughboro'-road, Brixton-road, on Monday, 30th September, 1844, at eleven o'clock, the whole of the NURSERY STOCK, consisting in choice Evergreens and Flowering Shrubs, Standard and Dwarf Roses; also two newly-erected Greenhouses, Frames, about 2000 Greenhouse Plants, a quantity of Rock Work, Utensils in Trade, &c.; may be viewed prior to the sale. Catalogues may be had on the premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone.

FREEHOLD NURSERY-GROUND, ST. ALBAN'S, HERTS.

MESSRS. PROTHEROE & MORRIS have received instructions from the Executors of the late Mr. Robert Fullwood, the mortgagee, to submit to public competition at the Auction Mart, Bartholomew-lane, on Thursday, 3d October, 1844, at One o'clock, THE KEY FIELD NURSERY AND NURSERY PREMISES, adjoining the town of St. Alban's, comprising a comfortable and convenient Dwelling-house and Shop, fronting the High Road from St. Alban's to London, and about six acres of very productive Nursery and Garden Ground. The whole Freehold and Land-Tax redeemed, and immediate possession may be had. The Premises were late in the occupation of Mr. David Watson, who for many years and up to the period of his death carried on the business of a Nursery and Seedsman. May be viewed at any time, and particulars had at the principal Inns in the neighbourhood, at the Auction Mart, of J. S. Story, Esq., Solicitor, St. Alban's; of George Drew, Esq., 185, Bermondsey-street, Borough; and of the Auctioneers, Leytonstone, Essex.

BUNNEY'S FINAL SALE.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, BUILDERS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor (in consequence of the Lease having expired), to submit to Public Competition by Auction, on the Premises, Kingsland Nursery, Balls Pond-road, on Monday, Oct. 7, 1844, and following days, at Eleven o'Clock each day without reserve, the whole of the valuable NURSERY STOCK, consisting of FRUIT and FOREST TREES, a considerable quantity of EVERGREENS, AMERICAN PLANTS, STOOLS, &c. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their Grounds; also the Trade, from its excellence, and comprising an excellent collection of Ghent AZALEAS, MAGNOLIAS, RHODODENDRONS, &c. May be viewed prior to Sale. Catalogues may be had on the Premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone.

MANSION, MANORS, AND ESTATE, IN KENT, TO BE LET,

MAYTHAM HALL, near Rolvenden, ten miles from the Staplehurst Station, on the London and Dover Railway, and two miles from the Tenterden Station on the projected Rye and Hastings Branch.

The MANSION, with beautiful Pleasure Grounds, productive Gardens, Pinery with Vines, Melon and Forcing Ground, Fruit Walls, and extensive Orchard, is delightfully situate in a finely timbered Park, commanding most extensive and highly picturesque prospects.

The MANORS, comprising from 1500 to 2000 acres, have been strictly preserved for many years past, and not having been much shot over last season, are now well stocked with pheasants, partridges, hares, and rabbits.

The MANSION is elegantly furnished, and adapted for a nobleman or gentleman of opulence, and is capable of accommodating a numerous establishment.

A tenant may be accommodated in a short time with any quantity of land he may desire.

May be viewed with tickets only, which, with particulars, may be had of Mr. P. K. Bearden, Solicitor, Birkenhead.

BICKLEY PARK MANSION, BROMLEY, KENT.
IMPORTANT SALE.

MR. SEPPINGS is again honoured with Instructions from the Proprietor to proclaim, by Advertisement, that he will SELL BY PUBLIC AUCTION, upon the PREMISES (in consequence of the Mansion being let), on Monday, September 16th, 1844, and Five following days, at 11 for 12 o'clock precisely each day, some splendid Oil Paintings by Lee, valuable Engravings and Prints, excellent Bed and Table Linen, costly and substantial Furniture, a Patent Grand Pianoforte by Broadwood and Sons, a variety of Cut and Plain Glass, Dinner, Tea, and Coffee Services, Kitchen requisites, &c. Also a large and choice Collection of Greenhouse and other Plants, consisting of very fine specimens of Camellias, Ericas, Chinese Azaleas, Cactus, Bed of Tulips, and a variety of other rare Plants, with a large Assortment of Flower-pots, Garden utensils, Hand-glasses of various sizes, Cucumber-frames, with lights, &c. Late the property of John Wells, Esq.

Cards of permission to view the Property, and Descriptive Catalogues, may be had by personal application, or by letter, postage-free, on the Wednesday, Thursday, and Friday previous to the Sale, of Mr. Fawley, White Hart Hotel, and Mr. Baxter, Druggist, Bromley; at Mr. Hitchcock's, Gray's-Inn Coffee-House, Holborn, London; at the Offices of Messrs. Seppings, and Jones, 1 Exchange-street, Norwich; and at the Terrace, Swaffham, Norfolk.

RAY SOCIETY, instituted 2d February, 1844.—This Society has been formed upon the principle of the Parker, Camden, Sydenham, and other Societies, for the purpose of securing to those attached to the study of Natural History, such Works on the various branches of Zoology and Botany as could not be obtained by other means; and will consist of original works; of new editions of works of established merit; of rare tracts and MSS.; and of translations and reprints of foreign works. Every subscriber of one guinea annually will be considered a member of the Society, and will be entitled to a copy of every work published by the Society. The Council have great pleasure in stating that the number of Members already exceeds 300, and beg to call the attention of their friends to the necessity of sending in their names as early as possible, in order that they may be enabled to determine the number of copies of their works which they ought to print. The Council hope to publish two volumes before Christmas, the first of which will consist of translations from the German and Italian, of Reports on the progress of Zoology and Botany during the last few years.

Communications on the business of the Society are requested to be addressed to the Secretaries, Dr. George Johnston, Berwick-upon-Tweed, and Dr. Lankester, Golden-square, London. Subscriptions to be sent, by post-office order or check, to the Treasurer, J. S. Bowerbank, Esq., 45, Park-street, Islington.

GEORGE JOHNSTONE, M.D.
EDWIN LANKESTER, M.D. } Secretaries.

The Gardeners' Chronicle.

SATURDAY, SEPTEMBER 14, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

TUESDAY, Sept. 17 South London Floricultural . 1 P.M.
SATURDAY, Sept. 21 Royal Botanic . . . 4 P.M.
COUNTRY SHOW.—TUESDAY, Sept. 17 . Midhurst Horticultural.

FIFTEEN pounds and a quarter avoirdupois was the WEIGHT OF A PROVIDENCE PINE-APPLE presented to Her Majesty the other day by the Baroness de Rothschild; fourteen pounds and a quarter was the weight of another exhibited by this lady's gardener, to the Horticultural Society; eleven pounds eight ounces was that of a third; and two others, each weighing ten pounds and three quarters, were cut green, and sent to France. Supposing that each of the latter would have gained only four ounces in weight (and it would be more reasonable to assume that they would have weighed one pound four ounces more), we have the incredible fact of five Pine-apples weighing sixty-three pounds.

This extraordinary result has been obtained by Mr. George Mills, so well known for his great success in Cucumber-growing; and his name is thus imperishably connected with the history of Horticulture, whose annals record no such event in former days. We have heard, indeed, of thirteen-and-a-half pounds having been the weight of one single Pine; but who before could boast of five huge Pines at one cutting, the lightest of which is almost without a parallel? Let it be remembered, too, that these were no monsters, half-green and half-ripe, with a swelling on one side and a paralytic affection on the other,—with one pound of stalk and two pounds of gills and crown—but honest thoroughly well-grown fruit, with all the parts well-proportioned, and a skin so full of juice, that the pips were puffed and swollen with its enormous accumulation.

And how has this been done? By disrooting and re-rooting? By shifting and re-shifting? By coaxing the unhappy plants to grow, and then cutting off their means of existence? By potting and re-potting, and potting again? By skinning a rich old pasture and carting the fee-simple of an acre into the potting-shed? By the aid of succession-pits, and succession-houses, and fruiting-houses? Of steam, hot-water pipes, or tanks? Of an apparatus, which no one without the revenues of a Rothschild could dare to think about? Not at all. By no such appliances; by nothing more important than a pigeon-holed Cucumber-pit, peat, and GOOD GARDENING. By what, in fact, every farmer can command, except the last; and that, it must be confessed, is rather important.

Without pretending to be better informed than our neighbours, or to have access to information which is not current all round the neighbourhood of Madame de Rothschild's residence, we will undertake to say that the following is very nearly the plan pursued by Mr. Mills. Conceive a sunk brick-pit, some eleven feet long and three feet wide, built of 4-inch brick-work, and pigeon-holed for three or four courses at the bottom. Let this be covered with common Cucumber sashes, and surrounded by hot dung. Then let us suppose that rough faggots or the larger boughs of trees are thrown into the bottom of such a pit to the depth of a foot, over which peat is laid to the same thickness. And now all being ready, suppose that a healthy sucker of a Pine is planted in this soil under the centre of each Cucumber light, and, unless we are much mistaken, we have the whole of Mr. Mills's preparation, except the good gardening, which neither bricks, nor faggots, nor soil, nor heating materials, can form, however much they may assist it.

Let not our country readers be incredulous about all this. What we have seen with our own eyes we may venture upon recording; and yet we should be disposed to pardon those who, in the face of such a statement, should exclaim, "I would not believe that, not even though I saw it myself;" for it does seem impossible to those who have been accustomed to ordinary Pine cultivation. We shall, however, surprise them still more when we add, that we are not yet satisfied. Great as Mr. Mills's success has been—and too much honour cannot be given to him for it—it is not great enough. Pines may be grown still larger and better; and we shall never rest contented till we see a Providence weighing 20 lbs. Then, and then only, shall we believe that growing Pine-apples will go no further.

Now that the HYACINTH SEASON is at hand, it is as well to remind our readers what they are to do in order to obtain good flowers.

Pick firm, plump bulbs, as round as may be. These are always the soundest, and are not likely to damp off.

When they are placed in glasses, take care that the water does not come within one inch of the bulb; put them in a dark closet that is rather warm, or, which is better, wrap them all over the glass and bulb, with old flannel, and keep them in a warm place till the roots are an inch long at least. Some recommend that the glasses should be dark; but that is of little consequence, provided the place in which the bulbs are set to root is dark.

The reason for this very important rule is, that roots should always be formed before leaves; otherwise, when the latter begin to grow they have nothing to feed them. Nature is most careful about this, as we may see when a seed begins to germinate and a tree begins to fruit. But ignorant people pop their bulbs at once into a glass of water, place it in a window, or upon a mantel-shelf, where light has free access, and the consequence is, that roots, which abhor light, will not come, while leaves, who love the light, rush forward to enjoy it. Then follows a long cluster of foliage, and a top-heavy plant, which when it does flower, if it ever gets so far, topples over every time it is jarred or disturbed. Get plenty of roots first, and leaves and flowers will take care of themselves.

The reason why the water should not touch the bulbs is, that if the plant is slow in growing, the organisable matter of the bulb is distended with fluid before it can decompose it, and so becomes putrid, when it communicates disease in all directions by virtue of its contagious properties. On the contrary, if the roots are active, and the leaves are beginning to grow, what water is taken up is immediately converted into some of the matter that Hyacinths feed on.

After roots have made a fair appearance water may be allowed to reach their tips, but not sooner, and it is only when the leaves are green and unfolding that it should be permitted to touch the bulb.

At that time, that is to say when the leaves are green, a lump of charcoal as large as an egg may be advantageously dropped into the water. It will prevent the water becoming putrid, and will, besides, act as a manure.

None of these precautions can, however, be of any avail unless the Hyacinths are kept close to the light continually, from the time when the leaves are first turned green. Thus, and thus only, will a healthy growth be preserved, and a fine vigorous head of flowers insured. Above all things, too, be careful to make the plants grow as slowly as possible at first, so as to accumulate vigour against the blooming season.

ENTOMOLOGY.

SURFACE-GRUBS and *surface caterpillars* are terms applied by gardeners to the larvæ of several night-flying moths, and amongst them are Noctua (Agrotis) exclamationis, and N. segetum, which bear the English appellations of the Heart and Dart, and the Common Dart moths, amongst collectors. As these caterpillars have made their appearance in great force in many parts of the kingdom, and numerous inquiries have been made respecting them, I lose no time in addressing the cultivator upon the subject, hoping that by calling his attention to their economy, his efforts to check their ravages may be successfully directed.

All the caterpillars called surface-grubs are exceedingly destructive to various crops, both in the field and garden, frequently devastating entire fields of Turnips and Mangold Wurzel, and not sparing the Potatoes. The larvæ first attack the Turnips in July, and destroy the plants by eating off the crown (fig. 2); in the two following months they sometimes swarm in fields, eating into the bulbs, and rendering them, to a great extent, unfit for use. I have known the Mangold Wurzel suffer severely in June, from these caterpillars biting through the roots, just below the surface of the soil; and they will attack the Potatoes when first pushing out of the ground. At night I believe they sally forth to feed upon the leaves, and after detaching them they are often dragged to their burrows, which resemble those of the earth-worm, and being drawn in, they are enabled to feed in security, and protected from the rays of the sun during the day—for they shun both light and heat. Having decapitated one young plant, the caterpillar directs his course to another with extraordinary rapidity, and thus destroys many more than he can consume for food. Later in the year, when the Turnip crop is more advanced, multitudes congregate round the plants, 10 or 12 being sometimes found about a single bulb.

The Surface Caterpillars transmitted to me this summer from many different localities were those of the Noctua exclamationis and N. segetum, which are equally mischievous, and very similar in appearance; they walk very fast, curl themselves up when disturbed, but speedily become active again, and bury themselves in a few seconds. Where the eggs of N. exclamationis are laid has not been recorded, but it is stated that the moth of N. segetum deposits hers in the earth. The caterpillar of the former is somewhat cylindrical, but a little depressed above, having six pectoral, eight abdominal, and two anal feet; it is of a dull lilac colour, with a broad paler stripe down the back, the margins of which form a darker line along each side, and there is a double dorsal line extending the whole length; the head is horny and brown; the minute eyes and two curved lines, as well as the jaws, are black; the first thoracic segment is rather horny and dotted; the following segments have four little tubercles on each, producing hairs, as well as similar ones on the sides; the stigma black (fig. 1). When full fed it is an inch and a half in length, and buries itself, forming an oval cell of earth, in which it changes to a shining rust-coloured chrysalis (fig. 3) to pass the winter in, and the following June, or perhaps earlier, the moth hatches. By Linnæus it was named Noctua exclamationis, and is now a member of that vast family, but called Agrotis,* and by English collectors the Heart and Dart moth. It is of a clay-colour, the wings reposing horizontally (fig. 4); the horns are like bristles, but slightly pectinated in the males; the tongue is long; on the front of the thorax is a transverse dark patch; on the upper wings there are two waved lines near the base; to the second is attached a long, longitudinal, deep-brown streak; above it is a spot varying in size and form, and beyond it a large kidney-shaped one; then follow a transverse, pale, waved line; and near the cilia is a more irregular one; the under wings are white, the upper margin and nervures brown; but in the female these wings are entirely dark-brown; their expanse is 1⅝ inch.

The caterpillar of A. segetum is more cylindrical than the foregoing species; the sides are greener, and there are three black dots by the stigma; but for the present I must refer the reader to the "Royal Agricultural Journal" for figures and descriptions of this species.†

It has been pretty well ascertained that salt and water will drive away these caterpillars; lime-water, and an infusion of Tobacco, are also distasteful to them. It appears that soot would be a great protection to Turnips and Cabbage crops, if applied early in the year, and laid an inch thick on the surface. If 1 lb. of soap be dissolved in 16 gallons of soft water, and applied warm to the infested ground, especially round the roots, the Surface Caterpillars will dart out of their burrows, and may thus be readily collected; but no time must be lost, as they will retire under-ground as soon as its effects have subsided. Hand-picking is also unquestionably the most effective means of ridding a field of this pest; it may be carried into effect either at night, when they come out to feed, or by day they may be searched for under stones and clods, and if the earth be scraped away from the bulbs, multitudes will be discovered in an infested field. Ducks and poultry would also assist in reducing their numbers. The pupæ are so securely protected in their tombs that it is perhaps impossible to assail them, and any means of attracting the moths at night by fires, by old sugar hogsheads, or boards smeared with beer and sugar, although it might tend to the capture and destruction of vast numbers, yet it would effect little, it is to be feared, as the males alone would thus fall a sacrifice, the females remaining, with few exceptions, in obscurity.—*Ruricola.*

ROSE GARDEN.—No. XVIII.

(*Continued from page* 604.)

Planting Out.—Having thus brought our subject to a close, as to the operative part, in preparing and perfecting the tree, it may not be amiss to spend a few moments in the consideration of the effect expected to be produced by it when planted out.

There are three causes of beauty in a tree—shape, foliage, and flowers. Shape (to a certain degree) is artificially obtained, foliage and flowers must depend upon species; the foliage is the more permanent, the flower the more striking. Planting out, then, must depend entirely upon the effect desired, and the taste of the party planting, as to variety of foliage, height, flower, its colour, and continuity; a tree with rambling shoots suits one place, and with a cauliflower head another. Tree Roses never look well in a round clump; they must

have a single appearance or be in some sort of line. If the effect of a sloping bank of Roses be desired, they must be planted in successive heights, viz. each under each; but if they are to have a less forced and regular appearance, and a more single and light look, an intermediate height may be left out, as thus: a two feet in front of a three feet, &c.

Be it observed, that a three-feet standard is most in keeping with the head it carries, and being nearer the ground has a very natural appearance, and in confined places is unquestionably the most desirable; but if the tree is to be distant from the eye, or the shrubbery or walk be large and increasing in distance, a four-feet standard is certainly more distinguishable, and has a much greater effect. A foot standard is of little or no use, except it be intended to approach the edge of a border, or is grafted for the convenience of affording nosegays, or increasing the quantity of the plant placed upon it. The heights most in use having been shown, it may be remarked, that for a weeping Rose to stand singly (perhaps surrounded with a wire guard and creepers upon it, to have a more marked effect), no stem can be found too high, if it be proportionally strong. A fine plant of this sort, six, seven, or even eight feet high, budded with a Noisette, or Boursault, looks beautiful, and its long free branches, covered with clusters of Roses, have a wild and luxuriant appearance, which give it a distinct and peculiar character. The trees being planted out and the earth made good around them, each tree must be supported by a neat clean hazel stake (unless the stock be so strong as not to require it), the top of which should be sawn off exactly level with the top of the wild stem, which conveys a great air of neatness, and attached to it with a piece of bass, or a small strip of pitched rope, which is still more durable.

Observations.—The following may be considered a more entertaining and less slovenly mode of propagating the Rose, as well as having the advantage of economy, as the cuttings of the pruned trees, which would otherwise be lost, are made use of. It must be remembered, however, that it should only be practised upon free, well-rooted stocks, as otherwise the delay in the rising of the sap, and the uncertainty of the supply, frequently defeat the purpose. Grafting, therefore, should succeed budding on the same stock, not precede it; as a bud failing on the stock, if the branch be not destroyed while the sap is up, leaves the stock still vigorous in the ground; if therefore this mode be preferred, it should be practised upon stocks that have had a spring to root themselves. The points to be desired are, that the barks of scion and stock should be cut quite smooth, and not separated from the wood they grow upon—that neither should be bruised—when they are put together should fit, close—a supply of sap should commence as soon as possible—that all sun, wind, and rain should be kept from the wound till healed, and that no ligament should be removed, nor shake given to the parts newly placed in contact, till they are perfectly healed; as any jar to the scion when placed is likely to defeat the purpose.

Home Correspondence.

Summer Pruning of the Vine.—In many places where I have visited of late, I have been surprised to see, generally speaking, such a total neglect in the summer pruning of this most generous of all our exotic fruits; it being, as it ought to be, well understood that, by kind treatment, there is no fruit-tree requiring artificial cultivation, the Peach-tree excepted, that will more easily bend to the will of the operator, nor produce more uniform crops of fruit. From the many articles that have appeared from time to time in the *Chronicle*, as well as in books treating exclusively on the culture of the Vine, I am surprised that the work of reformation has not commenced. Amateurs complain that year after year, even at a great expense for fuel, &c., they are never able to produce more than five, six, or seven bunches of Grapes upon each Vine, and of these, three or four bunches are at the extremity or top of the house, two or three in the middle, and the rest of the Vine is totally barren. The question that suggests itself to the mind of a practical man, on entering the houses of amateurs is, Why is each Vine allowed, as it were, to vie with its fellow in luxuriance, and to expend its strength, that ought to have been stored up in order to throw it into fruitfulness?—which no doubt every one would desire, but which it is quite clear is never attained; indeed, they have much the appearance of Vines planted out against some rustic seat, where they are allowed to ramble and luxuriate for the sake of displaying their foliage and tendrils. In some places where there is a scanty scattering of ill-ripened fruit, you find many of the spurs have never been stopped, but are allowed to run perhaps to the length of four feet; these again are loaded with laterals running right and left; others that have been stopped have in many cases sent out a host of laterals, each vying with the other in vigour similar to the common Hop in a hedge-row. If the question was asked, Why such is allowed to be the case? the answer is, "Oh, they are always the same; they are not good kinds; they never bear fruit, therefore we do not think that it is worth while spending time over them; at winter pruning we cut them well in, but they are still as you see, unfruitful. From such neglect it is clear that not one year in ten do they ripen their wood, from want of summer pruning. I would recommend instant application in removing all laterals and tendrils, not at one fell sweep (or the remedy might prove as bad as the disease), but by taking away a few each day, and in the course of a fortnight the Vines could be brought into a better state as regards the more perfectly ripening the wood, without which all labour will prove of no avail. Further, when the wood assumes a russet-brown, or approaches ripening, I would by all means recommend disbudding, as mentioned in my Treatise on the Vine, an operation ever attended with the best results, to Vines of any age, and one, in my opinion, that does not receive the attention which is due to it. If Vines are grown on the long rod system, leaving the eyes 18 or 20 inches apart on each side of the shoot, and all laterals have not been previously removed from each eye, but stopped at one joint, you will there find an eye upon each of them, which take out, leaving the leaves uninjured, with the exception of one or two at the extremity of the shoot. With regard to the spur system, choose a bold eye, third or fourth from the base of the spur, cutting all the others out above and below, with the exception of one well placed at the base, which must be retained in order to produce wood for the following year. I consider a fruitful eye on the Vine as easy to discern as a blossom-bud from a wood-bud on the Peach. A fruitful eye is round, plump, and well filled at the base of the leaf, whereas an unfruitful one is long and pointed. If the above hints were more generally practised by amateurs, they would have less cause to complain; for, by the above treatment (the roots in a proper state) they would be gladdened with more uniform crops of fruit annually, extending from below the angle of the rafter to the extremity of the Vine.—*James Roberts, Hampsthwaite, Harrowgate.*

The Robin.—In May last (see p. 335) I communicated some curious facts connected with the natural history of the robin—a bird to whose remarkable peculiarities, both in a wild and tame state, I have paid particular attention for the last six years. The anecdote I related to you, although authenticated by my name and address, has, I find, been by some doubted, by others marvelled at; nor is this, to me, a matter of surprise, for I verily believe the robin whose merits I record may justly rank as one of the wonders of the world. When last I addressed you my little friend was, as I mentioned, a denizen of the fields, the woods, and the orchards. Free as air he was roaming about with his fond mate and thriving young family (four in number), into whose infantine minds he was doubtless busily instilling a course of sound elementary instruction. These lectures have now terminated. His children, grown up, are gone abroad to see the world, and his ladye-love (as is the custom with these feathered songsters) has taken the veil for six long months. The consequence is, as I anticipated, a *réunion* between myself and this bird of song. No longer afraid, from prudential motives, of venturing too near the habitation of man, he re-appeared on Thursday, the 5th inst., *in propriâ personâ*, an independent, fearless bird. The friend and associate of my leisure moments (for I rise regularly at 5 A.M., to attend to my feathered family), he now comes at my call, however distant he may be. He sits on my finger and on the bridge of my nose, as of old; eats from my hand; sings like a seraph as he runs along the ground, and even allows me to play with him in my open hand, as he lies upon his back! In justice to my *protegé* I must add that his plumage is exquisitely bright, his eye beaming with intelligence, and his whole demeanour noble. Have we not here a convincing proof of the retentive memory, peculiar instinct, and remarkable affection of the robin?—*William Kidd, New-road, Hammersmith.*

Mulberry-tree.—On taking up a Broccoli plant that was recently planted, and which had sustained injury, I found a leaf-stem that had been half broken through, and the fractured part buried in the earth had sent out rootlets. It has been my practice in dibbling Kale plants to coil lengthy stems, which have always struck out roots at the bends. In planting out Cabbage with long stems I have nicked them in two or three places, with the same result. M. De Candolle observes in his "Organographie Végétale," vol. i. p. 246, "Une seconde circonstance, qui a engagé les naturalistes à admettre la prétendue identité des racines et des tiges, c'est la facilité avec laquelle l'un de ces organes donne naissance à l'autre." "Si l'on fait une ligature ou une incision à l'écorce d'un arbre il se forme au-dessus d'elle un bourrelet; si l'on enveloppe celui-ci de terre et de mousse humide il y pousse des racines."—"A second circumstance which has induced naturalists to admit of the supposed identity of the root with the stem is the ease with which one of these organs may be made to give being to the other." "If we attach a ligature or make an incision in the bark of a tree, a lump forms above it, and if this is surrounded with moist earth and moss it will send out roots." I imagine, therefore, that if the "Inquirer," (see p. 523,) who has a fine Mulberry tree upwards of 200 years old, is satisfied with its present locality, he may save himself the expense, labour, and risk of raising it, by making incisions in the stem in the part which will be below his new level; the communication of the leaf-roots being thus cut off from the tree-root will, attracted by the moisture of the new soil, strike into it, and the stem will thus send out lateral roots to seek any benefits that may be derived from proximity to the surface, while the original root will continue to draw water from below.—*John Goodiff, Granard.*

Song Birds.—I observe, with admiration, the humane remarks, thrice repeated, of your worthy correspondent, "J. M.," on the subject of wanton cruelty to birds. Too true it is that many hundreds of our choicest, prettiest warblers fall victims at this season of the year to the gun of the savage-breasted Cockney, or to the niggard parsimony of those heartless individuals who grudge the appropriation of a little paltry fruit, in return for the outpouring of hearts full of melody, gratitude, and love. Unfortunately I am myself among those who suffer from this devastation by beardless boys and Cockney sportsmen; but I am not altogether without a remedy; and this remedy I suggest to the notice of your correspondent "J. M." Let him, as I do, keep some choice blackbirds, thrushes, and other varieties of birds, in large, capacious cages (for confinement should not be made punishment) and let him hang them on the walls and trees of his garden. The song of these warblers will assuredly attract others; and by these means he may concentrate all the harmony of the feathered tribe in his own immediate locality, thereby protecting them from the danger of random shots, and from the cruel manœuvres of bird-catchers, bird-haters, and other similar "varmint," as "J. M.'s" enemy, the gamekeeper, has it. When thus assembled, the birds will come regularly to be fed on fruit, seed, bread-crumbs, or berries, and they will never stray further than is necessary for their further supplies of food. I am one of the true Waterton family; I never hear the report of a gun in the winter season but it goes to my heart. It is not a sufficient argument for me to be told that a man or a boy is a bad shot. By their want of skill their victims are too often maimed, when death would have been a blessing. Scandalous is it that humanity should be thus outraged, and that God's lovely and loving creatures should be thus wantonly deprived of their lawful, innocent enjoyment of life, to gratify the worst feelings of which human nature is susceptible.—*William Kidd, New-road, Hammersmith.*

Pruning Forest Trees.—From time to time articles have appeared in your columns, from the pens of various correspondents, advocating what I still call the pernicious and absurd practice of pruning forest-trees. I call it by these epithets in relation to the extent and the mode in which it has been heretofore recommended and practised, and not in regard to what I consider "judicious pruning," for which I am an advocate as well as those who have controverted my opinions. A writer, in your Number of July 27, who signs himself "W. H.," quotes a sentence of mine, I think rather incorrectly, viz.—that "I never saw a magnificent stem that had not a proportionally large head;" and proceeds to ask me whether I had not seen a magnificent head that had not a proportionally large stem? I answer, yes; and there are some specimens very near me now, and the cause of the disproportion is pruning—extreme pruning, vulgarly called pollarding. My opinion formerly expressed, and not correctly quoted by "W. H.," is—that I never saw a magnificent stem but what, at some period of its life, had a proportionally large head; for I have seen many magnificent stems with little or no head at all, but that is quite beside the question. Your correspondent is quite right in preserving any and every tree that is an ornament to his grounds, whatever its proportions. It is worth considering, however, whether his magnificent heads would not be quite as ornamental if they had also proportionally magnificent stems? I quite agree with "W. H." on the propriety of planting Oak wherever the character of the soil and other circumstances are favourable to its growth; not, however, to the exclusion of other things. I agree with him also as to the desirableness of clean, straight timber, for useful purposes, &c. I commend him for his attention to his plantations—a pleasing contrast to the general neglect and mistaken management we so often witness. His 40 years' experience entitles his opinion to respect; but, query—What is "judicious pruning?" It is a phrase, I fear, mistakenly—as it is variously—understood. Were "W. H." here, I could shew him abundance of Oaks out of which "the builder might cut his stout beam or girder," not only 25 or 30 feet, but 35 or 40—some even 50 feet, that, in all likelihood, were never touched by a pruning instrument in their lives. Now, again, what is "judicious pruning," and how long is it to continue? If those who are so zealous in advocating the process generally, would define what it is particularly,

and to what period of a tree's existence it is to be continued, we should then be able to form more correct ideas of how far "W. H." is justified in his concluding affirmation—"that increased vigour, stature, and bulk are its sure result;" a position which, though backed by 40 years' experience, I must still very seriously question.—*Quercus.*

Swan Marking.—For the sake of the reader who is unacquainted with what is called "swan marking," I shall briefly state how that is done, without entering into details as to when and how such laws or regulations relative to swans were established. When swans are kept on large streams by different proprietors, their servants meet about the last week in August, and besiege, as it were, the river, and cut the same kind of mark on the beaks of the young swans as that on the bills of the parent birds. They also pinion, or cut off the two first joints from one wing—one joint not being enough—then return the bird to the water. By that means each proprietor's swans are known. When it happens that swans belonging to different proprietors mate together, the brood are equally divided, the odd cygnet always going with the cock bird. In order to settle disputes, the old swans are caught and claimed by the marks already noticed. Some speak against pinioning of swans. I suspect, however, that the necessity of it is apparent; for, supposing they were not migratory, and had the use of their wings, is it likely they would suffer themselves to be caught by the neck with a crook, as a shepherd does his sheep? Even in the pinioned state it is attended with difficulty, especially in large rivers. On the Yare I lately observed a brood of 10 swans, being the greatest number I ever saw or heard of. Those acquainted with Ornithology know that our common swan is not identical with the wild sort that visits us in winter, but with what is called the mute swan common in Russia, and is met with in some parts of this country, without a master.—*J. Wighton.*

Strawberries, Asparagus, &c.—With all due deference to "Villagius," I must demur to the inferences contained in his letter last week. In nine cases out of ten, according to my experience, if you manage two Strawberry-beds in the same way—one bed being one, and the other three years old—you will have the best crop from the latter. Therefore it is quite clear, as his crops were equal according to superficial observation, his experiment proved against the mutilating, unscientific system of cutting off the lungs of the plants. Now, as to the time of applying salt to Asparagus, I have stated the result of practice, not theory. I have applied salt, after dressing in the autumn and early in the spring—1 lb. to the square yard—with the most striking advantage. Now the questions to decide upon this interesting subject are—1st, Do we actually apply the salt to the dormant root, by covering the surface in autumn? To this question I answer in the negative; inasmuch as the salt has to be washed through a considerable depth of soil before it reaches the root, and it is only reasonable to infer that when it does arrive there, its caustic character will have materially altered by dilution and chemical decomposition. 2d, Will not the salt do decided harm by being applied to the delicate green, living texture of the young shoots late in spring? Let "Villagius" try it, and I will wager him the best hat I cut next year that he will destroy or materially injure his plants. But, as I said before, I made my statement from practice, not theory. My beds are now looking beautiful, with lofty, flourishing plants. As soon as they begin to die back, I shall cut and dress them, and apply the salt as heretofore on the surface, to be gradually washed in by the winter rain. Should I fail, I hope "Villagius" will tell me where to send him the lost wager.—*C. R. Bree, Stowmarket.* [We quite agree.]

Toads and Frogs.—A few weeks ago, among "Notices to Correspondents," I observed an inquiry in reference to toads: the question was—Do they eat slugs? I am now enabled to say that they do. I am satisfied that they are carnivorous, and that they do not eat either fruit or vegetables. I referred to the "Penny Cyclopædia," and found an excellent article under the word "Frog." I there learned that they live on slugs and other small animals; that they take their prey with great rapidity and swallow it immediately, without mastication. I went into my garden, found a slug, and put it on the end of a stick, and gently introduced it before a toad; I kept my eye upon it, and soon it disappeared; and at the same time I saw the toad swallow: so rapidly, however, had the toad taken the slug in with his tongue, that I did not see it done. I believe both frogs and toads live on the pests of the garden. I am always glad to see them. Last summer I had many slugs, and they destroyed several crops; this summer I have had plenty of frogs and toads, and very few slugs.—*Jasper Stokes, Birmingham.*

Pine-apples.—As the system of growing and fruiting Pines without pots is becoming general, it is desirable to become acquainted with those substances which are most conducive to their growth. It is evident that Pines when planted out attain more robustness, and this mode is certainly more natural than that of confining them in pots; but whether it is more favourable to the production of larger fruit than the old plan, remains to a certain extent undecided. Pines will grow in any soil, and other plants will do the same, but the results will be different. A strong soil favours the production of large fruit, and in this the habit of the plant is more compact; a light substance, such as leaves or tan, has an opposite effect—the plant and fruit grow quite disproportionate. Pines growing in leaves half decomposed, will, in a given period, be larger plants than those growing in loam; the leaves are equally broad and the roots are more abundant, but they are altogether deficient in substance and compactness. I cannot suppose there is any advantage to be derived from laying up a heap of soil before it is wanted for use, particularly when a few inches only of the surface is taken. When spread about that depth it is more exposed to every atmospheric change than when it is in one mass and turned several times during a twelvemonth. In preparing a bed over a tank the first stratum should consist of rough gravel for two or three inches in depth; above that the same depth of leaves or other litter should be laid; then the last layers, consisting of two parts loam, one leaf-mould, and one horse-droppings, well mixed together, should be fifteen or eighteen inches in depth. Pines grown in such a compost, and duly attended to with heat, will reward the owner with excellent fruit. Sometime ago I was informed by a gentleman, lately residing in India, that in some of the Pine districts near the sea, where the soil is naturally strongly impregnated with saline substances, Pines flourish and produce enormous fruit. The ocean, at times, flows over the ground; probably, therefore, a little salt introduced into soil for Pines might prove efficacious to them. —*Mémet.*

Gray Parrot.—I have read the different statements respecting the treatment recommended for keeping a favourite bird from plucking off its feathers. My treatment in regard to its food is quite the reverse of many of your correspondents. I have two fine birds, which I have had for this last seven or eight years; their food has been bread and butter in the morning, meat two or three times a-day, or anything the family may have—such as Potatoes, pudding, cake, fish, fruit — everything except salt meat; that is avoided, if too salt. Their tins are filled with clean water every day, and their cages cleaned out and sand put in; they take tea, and spirits with water when given them; they are taken out on the hand every day, and fondled over two or three times to exercise their wings, which I consider is very beneficial to their health and the beauty of their plumage. I have never given them any seed or soaked bread. With the above treatment my birds have always been in good health; their plumage has always been good, and they have never lost their feathers till the time of moulting, and even then they have never looked unsightly.—*James Woods, Harwich, Essex.*

Variegated Leaves.—Mr. Groom has stated in last Number that the leaves of some of his Pelargoniums have become regularly edged with white in consequence of his having watered the plants with sulphate of ammonia which had been exposed to the air for some time. Last autumn I planted many young Box-trees; and I have for some weeks observed that nearly all the young leaves in most of them are symmetrically tipped with white, giving the young branches a mottled appearance. I counted twelve trees thus affected. The older leaves are rarely tipped, with the exception of two bushes, in which they are regularly tipped, and the younger ones much less so. Mr. Groom states that in his Pelargoniums the older leaves are chiefly affected. The Box-trees are quite healthy, and growing well. I gave to some of them nitrate of soda, but it has made no difference in this variegation. Those growing in deep shade are not tipped, nor are some older trees. These facts may appear trivial; but I think the first appearance, even if not permanent, of any peculiarity which tends to become hereditary (as I fear is the case with the variegated Sycamore) deserves being recorded. — *C. Darwin.* Mr. *H. W. Bucknall*, of Bedminster-lodge, Bristol, also forwarded leaves taken from three Greengage Plum-trees, which were regularly edged with yellow. Mr. Bucknall writes that the trees were watered with ammoniacal liquor diluted with five times its bulk of water by mistake, instead of ten times. The whole of the leaves of each tree have turned yellow round the edges, the rest remaining a healthy green. The trees perfected their fruit well, and are otherwise in good health. The same mixture, he adds, was used on Peaches and Nectarines, but did not affect them.

Lilium lancifolium album, &c.—In the spring of 1843 I paid three guineas for a flowering bulb of one of these fashionable Liliums, which flowered well, and also ripened a pot of seed, which I sowed in a shallow box; this was kept during the whole summer in a Melon-frame, and was watered and nursed with particular care. Notwithstanding this, however, not more than half a dozen plants ever appeared; these did not produce more than one leaf, and put forth small bulbs about the size of a grain of Wheat. After these were fully ripened, I proceeded to take them up, and in so doing I was surprised to find the whole of the soil in the box full of bulbs, superior even to those that appeared; they were an inch deep in the soil on which the seeds producing them had been laid upon the surface; the seeds, as they swelled by moisture, were barely covered. I have thus most unexpectedly found myself in possession of 180 bulbs; and I should like to know how these wholesale underground operations were conducted. This circumstance should induce others to examine narrowly their seed-pans before discarding them; as, before this was known to me, I am sure that I have sacrificed thousands of bulbs. —*N. M. T.*

Transmutation of Corn.—Is it possible that Wheat, Barley, and Oats, can change, from being kept from coming into ear? If so, then perhaps it may be true that Primroses, turned root upwards and made to grow so, become Cowslips. I have always laughed at the idea, but it is believed in some parts of Wiltshire. I have been also told that if single Primroses, Tulips, Polyanthuses, and Auriculas, are turned root upwards, they will become double in a year or two. Can it be? Mignionette kept from flowering for a year becomes a shrubby plant and perennial, but still it remains Mignionette, only much more powerful as to scent.—*A Non-believer.*

Wistaria sinensis.—I have a plant of this truly beautiful and ornamental climber, about five years old, which has been allowed to grow in a very irregular state; no attention has been paid to it during that period. Early in March of this year I thought, on seeing the noble specimen in the Horticultural Gardens at Chiswick, that something might be done to assist Nature in forming a similar specimen, in course of time, out of my deformed plant. Accordingly, I cut and trimmed all the branches to within a quarter of a foot of the stem, leaving two wood-buds, and also flower-buds, varying from one to three on each spur; after which it has bloomed well. About the middle of March I commenced giving it a plentiful supply of water, twice or three times a week. This I continued to do for about six weeks, occasionally loosening the ground about the roots, so as to prevent the earth becoming baked under the influence of a May sun. It went on growing, and still continues doing so; but two of the principal shoots, measuring 26 feet, the growth of this year, have turned by a freak of Nature into monstrosities as flat and about the same thickness as a penny-piece. They are about 7 feet in length, turning upwards and dividing into two branches at the extremity: one branch measures two and the other one foot from the division. Will you inform me what plan, under these circumstances, had better be adopted, in order to insure a healthy and vigorous growth next spring.—*T. D. Gordon.* [Your branch is what botanists call fasciculated; it is of no consequence, for the new branches, &c. will come from it all the same if you get it ripe. It arises from over-luxuriance.]

Country Shows.—We have a Society in our village, and on the morning of its July meeting I met a respectable tradesman whom I shall call Mr. Smith, and said: "Well, Mr. S., I suppose I shall see some of your plants at the Show to-day?" Mr. S. "No you won't, ma'am. What is the use of my sending plants when —— and —— and —— will beat me out and out? Haven't they the use of the greenhouse, stove, manures, and all that their masters' purse can buy; and what chance can I have with my frame only? Depend upon it, ma'am, those Horticultural Societies will not last long, if they don't alter! Now, if I had a chance of a prize I would send my plants, and I would take my family, and some of my friends would go too, and then they would get as many shillings towards their funds; but now I stay at home, or I go to the Stag and smoke my pipe instead." X. "Then you think there should be a prize for tradesmen, or those persons who possess a frame only?" Mr. S. "Certainly I do; but, bless you, they'll never do anything till they let the women have a share." X. "Then you think there should be a lady's prize?" Mr. S. "No, I don't mean quite that—I mean that there should be prizes for women only; let there be two of them—one for ladies, and the other for women in a lower rank, or it will be just the same as it is now with the men. Why, ma'am, it would do no end of good; instead of being stitch, stitch, stitch, all day long at that worsted-work, why they would get out into the air, and it would do them a world of good." X. "Well, Mr. S., I should be glad to see your suggestions carried into effect; but I fear——" Mr. S. "Ah, well, ma'am, all I can say is, that if something is not done our Society will die of consumption; and if they will only use a little common sense about their rules, why they will prevent consumption in others, for instead of spending our evenings at a tavern, we should be tending our plants." We then separated, and I send Mr. Smith's hints, as showing what I know to be general sentiments respecting garden societies.—*X.*

Onions.—A piece of garden ground, 13 yards long, and 4 feet wide, cultivated by Mr. Everitt, gr. to D. Hoste, Esq., Barwick House, Norfolk, produced this year 28 st. 12 lbs. of White Spanish Onions. Is not this an unusually fine crop?—*W. E.*—[Very.]

Wasps.—A few weeks since I observed in the *Chronicle* a statement made by a correspondent to the effect that a wasps' nest might be easily destroyed by means of turpentine. I have since tried the experiment, and, in accordance with your correspondent's directions, I inserted the neck of a bottle containing a small quantity of turpentine into the mouth of the hole, and plaistered it round with clay. The result was, that it not only did not destroy the nest, but the next morning a wasp, perfectly alive, actually came out from the bottle! I wish to know wherein I was wrong in making my experiment, and how your correspondent reconciles this fact with his former statement.—*H. P.* [Spirits of turpentine poured into wasps' holes will certainly kill them; the bottle experiment we have not tried].

Growth of Trees.—Respecting the elongation of the spaces between the tiers of branches on a tree after they are formed, it is said, that after a year's stem-shoot is fully formed, it will elongate, and that a side-branch at one time—say any given number of feet from the ground—shall in a few years afterwards be raised considerably higher from the surface. Whoever defends such a notion has surely never attentively observed the growth of trees. Take a Fir, for instance, after it has been planted, even 20 or more years, it will be found that the lower branches are as close to the surface of the ground as when it was planted, and of course the distance between each successive tier of branches remains of the same length, as those spaces never elongate after they are formed.—*W. Billington.*

COUNTRY SHOWS.

Bury Floral and Horticultural Society, Aug. 21.—This was the second meeting for the exhibition of Carnations, Picotees, Stove and Greenhouse-plants, Dahlias, Fruits, and Vegetables, &c. It was held in the Victoria Gardens. The morning was rather unfavourable; but the number of articles for exhibition was, nevertheless, so numerous, that the marquee, which is 22 yds. long by 16 yds. wide, was scarcely large enough to contain them. We were pleased to see the Cottagers had taken the advantage of the opportunity offered them to contend for the prizes given by the Society. Thirty-eight exhibited in this class, and their productions did honour both to their table and the exhibition. We hope that the success which has attended the Exhibitors in the Cottager's class will be the means of making many earnestly set about cultivating their little gardens and bringing their productions to future Exhibitions. The wealthier classes expressed their astonishment at seeing such good fruit, flowers, and vegetables as were exhibited on the Cottager's table, and are anxious to afford them every means of encouragement. The prizes were awarded as follows: CARNATIONS—*Scarlet Bizarre*: 1, Ely's Jolly Dragoon, Mr. J. Cheetham; 2, Omnium Primum, Colonel Lee; 3, Kershaw's Duke of Richmond, Mr. W. Leach; 4, Duke of Leeds, Mr. J. Cheetham; 5, Don John, Mr. J. Cheetham; 6, Gameboy, Mr. R. J. Kaye. *Crimson Bizarre*: 1, Lord Milton, Mr. W. Cheetham; 2, Paul Pry, Colonel Lee; 3, Seedling, Mr. J. Hurdman; 4, King Alfred, 5, William Caxton, 6, Rainbow, Colonel Lee. *Scarlet Flakes*: 1, Chadwick's Brilliant, 2, William the Fourth, 3, Ringleader, Colonel Lee; 4, Potter's Champion, Mr. J. Scholes; 5, Beauty of Bradley, Mr. R. J. Kaye; 6, Marquis of Granby, Colonel Lee. *Rose Flakes*: 1, Duchess of Devonshire, Colonel Lee; 2, Lovely Ann, Mr. R. J. Kaye; 3, Duchess of Sutherland, Mr. Holland; 4, Apollo, Mr. R. J. Kaye; 5, Dobbin's Mountaineer, Colonel Lee; 6, Lady Ely, Mr. Dunderdale. *Purple Flakes*: 1, Euclid, 2, Princess Charlotte, Colonel Lee, 3, Elizabeth, Mr. J. Hurdman; 4, Bellerophon, 5, Mungo, 6, Commander, Colonel Lee. PICOTEES—*Purple, heavy-edge*: 1, Nulli Secundus, Mr. J. Cheetham; 2, Beauty of Wurley, Mr. R. J. Kaye; 3, Victory, 4, Bonny Bet, Mr. W. Leach; 5, Kaye's Monarch, 6, Jackson's Delight, Col. Lee. *Purple, light-edge*: 1, Nulli Secundus, Mr. W. Leach; 2, Field Marshal, Mr. T. Smith; 3, Grace Darling, Mr. W. Lodge, 4, Prince Albert, Mr. J. Scholes; 5, Royal Adelaide, Mr. W. Lodge; 6, Seedling, Mr. Holland. *Red, heavy-edge*: 1, Duchess of Cambridge, Mr. R. J. Kaye, 2, Marshal Soult, Mr. Holland; 3, Marc Antony, Colonel Lee; 4, Mrs. Horner, Mr. Lodge; 5, Little Wonder, Colonel Lee; 6, Duke of Wellington, Mr. R. J. Kaye. *Red, light-edge*: 1, Mrs. Maynell, Mr. Holland; 2, Mrs. Horner, 3, Nonpareil, Colonel Lee; 4, La Superb, Mr. Lodge; 5, Princess Sophia, Mr. Holland; 6, William the Conqueror, Mr. R. J. Kaye. DAHLIAS—*Dark*: 1, Essex Triumph, H. Openshaw, Esq.; 2, Garrick, A. Wood, Esq.; 3, Standard of Perfection, 4, Sir R. Sale, Mr. J. Gaskell. *White or Blush*: 1, Antigonist, 2, Emma Noke, Mr. Gaskell; 3, Lewisham Rival, 4, Coronation, A. Wood, Esq. *Yellow or Orange*: 1, Aurantia, Mr. Lodge; 2, Argo, Mr. Gaskell, 3, Parkmount Rival, Mr. Lodge; 4, Lady Stamford, Mr. Gaskell. *Lilac or Purple*: 1, Standard of Perfection, Mr. C. Noyes; 2, North Midland, Mr. Lodge; 3, Lady Harlam, H. Openshaw, Esq.; 4, Pickwick, Mr. Gaskell. *Scarlet and Red*: 1, Eclipse, 2, Tournament, Mr. Gaskell; 3, Duke of Cornwall, H. Openshaw, Esq.; 4, Scarlet Defiance, Mr. T. Davenport. *Rose and Crimson*: 1, Attilla, 2, Miss Abbot, Mr. Gaskell; 3, Mrs. Shelley, Mr. J. Ashworth; 4, Competitor, H. Openshaw, Esq. *Edged and Tipped*: 1, Lady Antrobus, Mr. C. Noyes; 2, Beauty of the Plain, Mr. Lodge; 3, Lady Antrobus, Mr. T. Davenport; 4, Madame Chouvieri, Mr. Lodge. AMATEURS—24 *varieties*: Mr. T. Davenport. AMATEURS AND GENTLEMEN'S GARDENERS—12 *varieties*: 1, H. Openshaw, Esq.; 2 and 3, Mr. J. Gaskell. GREENHOUSE PLANTS: 1, Mr. Thos. Davenport; 2, Daniel Grant, Esq. *Single Specimens*: 1, Lilium lancifolium, Mrs. Ramsbottom; 2, Helichrysum proliferum, R. Ashton, Esq.; 3, Fuchsia formosa elegans, Mr. T. Davenport; 4, Rose Louis-Philippe, 5, Rosa odorata, Miss Grundy. STOVE PLANTS—1, Luntana manionina, L. crocea, Nerium [illegible] 2, Gloxinia tubiflore Thu[illegible] crenulata, R. Ashton, Esq.; [illegible]ata, &c., D. Grant, Esq. *Single Specimens*: 1, Thunbergia alba, J. Fenton, Esq.; 2, Achimenes pedunculata, R. Ashton, Esq.; 3, Zygopetalum maxillare, J. Fenton, Esq.; 4, Cockscomb, Mr. Gaskell; 5, Ardisia crenulata, D. Grant, Esq. *Pansies*, 24 *varieties*: 1, Mr. T. Cross; 2, Mr. N. Cronshaw; 3, Mr. Cross, 4, Mr. Noyes. 12 *varieties*: 1 and 2, Mr. N. Cronshaw; 3, Mr. Cross; 4, Mr. N. Cronshaw. *Pines*: 1 and 2, Providence, 3, Montserrat, J. Fenton, Esq. *Black Grapes*, 1, Lombardy, J. Fenton, Esq.; 2, do., Mrs. Ramsbottom; 3, Black Hamburgh, D. Grant, Esq. *White Grapes*: 1, White Muscat, D. Grant, Esq.; 2, do., Mrs. Ramsbottom; 3 do., Mr. Richardson. *Melon*: 1, Mr. Noyes; 2, Cantaloupe, D. Grant, Esq.; 3, J. Fenton, Esq. *Peaches*: 1 and 2, D. Grant, Esq.; 3, Miss Grundy. *Nectarines*: 1 and 2, D. Grant, Esq.; 3, Miss Grundy. *Apricots*: Miss Grundy. *Plums*: D. Grant, Esq. *Dessert Apples*: Mr. Cross. *Culinary Apples*: 1, Mr. Noyes; 2, Mr. Cross; 3, R. J. Grundy, Esq. *Dessert Pears*: 1, R. Hucking, Esq.; 2, Miss Grundy; 3, Mr. Noyes. *Culinary Pears*: 1, Mr. Noyes; 2, Mr. Cross, 3, R. Hucking, Esq. *Alpine Strawberries*, J. Faulkner. *Orange tree in fruit*: 1, D. Grant, Esq.; 2, Mrs. Ramsbottom. *Lemon tree*: 1, Mr. Richardson. *Cucumber*: 1 and 2, Mrs. Ramsbottom; 3, R. Ashton, Esq. *Mushrooms*: 1 and 2, R. Ashton, Esq.; 3, J. W. Swannick, Esq. *Peas*: 1, Mr. Davenport; 2, A. Wood, Esq.; 3, Mr. Ashworth. *Broad Beans*: 1, Mr. Cross; 2, Mr. C. Jackson; 3, R. Hucking, Esq. *Kidney Beans*: 1, Mr. Faulkner; 2, A. Wood, Esq.; 3, D. Grant, Esq. *Celery*: 1 and 2, A. Wood, Esq.; 3, Mr. J. W. Swannick. *Cauliflower*: 1, Mr. Faulkner; 2, Mrs. Ramsbottom; 3, Mr. Faulkner. *Broccoli*: 1 and 2, J. Fenton, Esq.; 3, D. Grant, Esq. *Cabbage*, 1, Mr. J. W. Swannick, 2 and 3, R. Hucking, Esq. *Red Cabbage*: 1, Mrs. Ramsbottom; 2, R. Ashton, Esq. *Parsnips*: 1, Mr. G. Jackson; 2, J. Fenton, Esq. *Turnips*: D. Grant, Esq. *Carrots*: D. Grant, Esq. *Artichokes* 1, J. Fenton, Esq.; 2, Mr. Noyes. *Beet-root*: 1, D. Grant, Esq.; 2, J. Fenton, Esq. *Onions* (Autumn-sown), Mr. J. Jackson. (Spring-sown): 1, Mr. Noyes; 2, Mr. Cross; 3, Mr. H. Smith. *Endive*: Mr. J. W. Swannick. *Parsley*: 1, A. Wood, Esq.; 2, D. Grant, Esq. *Lettuce*: 1, R. Ashton, Esq.; 2, J. Fenton, Esq. COTTAGERS—*Pelargoniums*: 1, T. Holt; 2 and 3, T. Allen. *Dahlias*: J. Sykes. *Apples*: 1, J. Foster; 2, T. Greenhalgh; 3, J. Knott. *Pears*: 1, J. Foster; 2, T. Booth; 3, T. Greenhalgh. *Plums*: T. Greenhalgh. *Peas*: 1, R. Olivant; 2, T. Booth; 3, J. Chatterton. *Beans*: 1, R. Pickstones; 2, C. Hilton; 3, A. Taylor. *Celery*: J. Kaye. *Cabbage*: W. Tweedale. *Red*: 1, T. Pollett; 2 and 3, T. Booth. *Carrots*: 1, J. Fletcher; 2, M. Mullet; 3, J. Sykes. *Turnips*: 1, D. Astley; 2, H. Partington; 3, M. Mullett. *Onions*: 1, J. Pollett; 2, W. Bowker; 3, T. Pollett. *Lettuce*: T. Booth. *Parsley*: T. Booth. [We have inserted this at the particular request of the reporter; but we cannot again depart from our rule of excluding reports without the names of the flowers or fruit that win.]

Hunts. Horticultural Society.—This was the annual Show of the Huntingdonshire Horticultural Society: the display of fruit and flowers was small compared with former years.—CARNATIONS.—*Scarlet Bizarre*: 1, Barringer's Fair King, Mr. F. Barringer; 2, Hepworth's Leader, Mr. Giddings; 3, ditto, Mr. J. Barringer. *Purple*: 1, Barringer's Surprise, Mr. J. Barringer; 2, ditto, Mr. Wood. *Flake Scarlet*: 1, Lydia, Mr. F. Barringer; 2, ditto, Mr. J. Barringer. *Purple*: 1, Beauty of Woodhouse, Mr. F. Barringer; 2, Queen of Sheba, Mr. Franklin; 3, Barringer's Apollo, Mr. F. Barringer; 2, ditto, Mr. J. Barringer; 3, Sir George Grewe, Mr. Franklin; 4, Barringer's Apollo, Mr. F. Barringer. PICOTEES.—*Purple*: 1, Wood's Princess Alice, Mr. Wood. *Dark Red*: Duke of Wellington, Mr. Franklin; 2, ditto, Mr. F. Barringer; 3, Sir Robert Peel, Mr. Giddings. *Scarlet or Pale Red*: 1, Sir Robert Peel, Mr. Barringer; 2, Duchess of Sutherland, Mr. Franklin; 3, Hector, Mr. Franklin. *Rose*: 1, Queen Victoria, Mr. J. Barringer. *Yellow*: 1, Maid of Middelburgh, Mr. J. Barringer. *Best Picotee, by Amateurs*: Queen Victoria, Mr. Price. GOOSEBERRIES.—*Heaviest Red*: 1, Wonderful, Mr. Giddings; 2, ditto, Mr. Giddings. *Yellow*: 1, Piggot's Leader, Mr. Giddings. *Green*: 1, Plumper, Mr. Giddings. *White*: 1, Ostrich, Mr. Newman. *Extra Prizes* were given to Mr. Slight for a beautiful Achimenes grandiflora; to Mr. J. Barringer for Cockscombs; and to Mr. Giddings for Ritou Strawberries.—*Cambridge Chronicle.*

Isle of Wight Horticultural Society, Aug. 26.—This was the second and last Exhibition for the season. The Prizes were awarded as follows:—*Stove or Greenhouse Plants.*—1, Mr. Barnicle, gr. to J. Percival, Esq., for Lisianthus Russellianus, Amaryllis striatiflora, Erythrina crista-galli, Hibiscus sinensis roseus, Hibiscus Cameroni, and Vinca alba; 2, Mr. Jobling, gr. to the Rev. A. Hewitt, for Statice arborea, Vallota purpurea, Crassula falcata, Gesnera zebrina, Achimenes pedunculata, and Clerodendron speciosissimum. *Twelve best Roses.*—1, Mr. Meehan, gr. to Col. Harcourt, for Lamarque, Emile Courtier, Jatifolia, Abbé Mirland, Lyonnais, Henri Berbet, Bernard, Dou Carlos, La Biche, Pourpré supérieur, Clara Sylvain, and De Neuilly; 2, Mr. Jobling for Jaune Desprez, Lady of the Lake, Aimée Vibert, Philip the First, Noisette multiflora, Lee's Crimson, Madame Desprez, Bougare, Hymenée, and Fabvier. *Fuchsias.*—1, Mr. Barnicle for Pageana, Coronet, Modesta, Vesta, Neptune, Coccinea, Toddiana, Moneypenii, magnifica, insignis, tricolor, and Albion; 2, Mr. Meehan for Eppsii, Defiance, Brockmanii, Exoniensis, St. Clare, Formosa elegans, Toudiana, magnifica, tricolor, conspicua arborea, transparens, and racemiflora. *Cockscombs.*—Mr. Bone, gr. to Mrs. Lind. *Dahlias.*—1, Mr. Bone for Squibb's Defiance, Princess Royal, Stella, Majestic, President of the West, Ne Plus Ultra, Scarlet Eclipse, Grace Darling, Lady Bathurst, Rival Sussex, Phenomenon, and Beauty of Sussex; 2, Mr. Barnicle for Springfield Rival, Admiral Stopford, Scarlet Defiance, Squibb's Defender, Virgin Queen, Marquess of Lothian, Bonaparte, Purple Perfection, Rival Sussex, and three seedlings. *German Asters.*—Mr. Jobling. *Verbenas.*—1, Mr. Barnicle for Boule de Feu, Queen, Bridesmaid, Stewart's Purple, Renown, Ingramii, Prince of Wales, Groomiana, Strata coccinea, Mortlock's Superb, Unique, and Buisii (these were in pots); 2, Mr. Jobling for Teucroides carnea, Unique, Groomiana, Stewart's Purple, Queen, Joan of Arc, Hendersonii, Melindres superba, Laconii, Lucisa, Ingramii, and Renown. *Seedling Pansy.*—Mr. Meehan for a dark variety. *Grapes.*—Mr. Jobling for Black Hamburgh. *White Grapes.*—1, Mr. Bone for White Sweetwater; 2, Mr. Barnicle for the same. *Peaches.*—1, Mr. Meehan for Chancellor; 2, Mr. Bone for Noblesse. *Nectarines.*—1, Mr. Meehan for Newington; 2, Mr. Jobling for White Nectarine. *Plums.*—1, Mr. Meehan for Greengages. *Apples.*—1, Mr. Thompson for Kerry Pippin; 2, Mr. Barnicle for Quarrenden. The following *Extra Prizes* were awarded:—To Mr. Bone for Balsams; to Mr. Meehan for a stand of 24 Pansies (chiefly seedlings), for Hollyhocks, and for a single specimen of Clerodendron speciosissimum; to Mr. Jobling for *Phloxes*, viz.: Wheelerii, Sheppardii, speciosa, omniflora, cordata grandiflora, excelsa, pendulifolia, Drummondii varieties, Pyramidalis, reflexa, and incarnata: to Mr. Barnicle for Gloxinia maculata, and for a seedling Dahlia (white, tipped with vermilion), for six Cockscombs, and for two bunches Black Hamburgh Grapes; to Mr. Thompson for six Newington Nectarines.

Morningside Practical Gardeners' Society.—This was the third meeting for the season. The following prizes were awarded:—*Seedling Pelargonium.*—1, Mr. J. Downie, gr. to General Robertson, for Miss Easton; 2, Mr. Gibb, gr. to Mrs. Stark, for Gem. *Seedling Pansy.*—1, Mr. Stevens, gr. to Alexander Russell, Esq., for Queen; 2, Mr. J. Downie for Little Wonder. *Roses.*—Mr. H. Gibb for Crested Moss, Madame Hardy, Village Maid, Louis-Philippe, Ne plus Ultra, and Fulgens. *Pinks.*—Mr. T. Ovens for Queen Victoria, Nimrod, Tweedside Beauty, Miss Brandland, Nymph, and Rainbow. *Verbenas.*—Mr. J. Downie for Vivid, Princess Royal, Burleyana, Tweediana picta, Howardii, and Ingramii. *Calceolarias.*—Mr. J. Downie for Standish, Duchess of Buccleuch, and Lady Constable. *Salvias.*—Mr. J. Downie for Fulgens, Patens, and Grahamii. *Picotees.* Mr. J. Young for Duchess of Kent, Incomparable, and Nulli Secundus. *China Asters.*—Mr. W. Denholm, gr. to Sir J. Forest, bart. *Stocks.*—Mr. J. Young. *Herbaceous Plants.*—Mr. J. Browne for Phlox omniflora, Delphinium Barlowii, Double Scarlet Lychnis, Lathyrus latifolius, Campanula grandis, and Cuclone barbata. *Grapes.*—Mr. J. Fergie for Black Hamburgh. *Melons.*—Mr. W. Denholm for Duke of Bedford. *Gooseberries.*—Mr. J. Gould for Porcupine. The Prize by Messrs. Dickson and Son, Nurserymen, Inverleith, for the best one-head of *Cauliflower*, was won by Mr. T. Wood, gr. to A. Falconar, Esq.—The Prize by Mr. M'Intosh, Agent for Messrs. W. Wood and Son, for the best 6 Roses, was won by Mr. J. Downie with Boule de Nanteuil, Kean, Triomphe de Montmorency, Bourbon Queen, Mousseline, and Louis-Philippe.—Mr. J. Gould, gr., Canaan Cottage, exhibited a very fine plant of a seedling Maurandya, for which an extra Prize was awarded.—There were also exhibited from Grange Bank some pretty seedling Pansies.

West Bromwich Floral and Horticultural Society, Sept. 20.—This, the first Exhibition of the Society, went off much better than was expected. A. Kenrick, Esq., sent a miscellaneous collection of stove and greenhouse plants, not for competition, amongst which were fine plants of Gesnera zebrina, Achimenes grandiflora, longiflora, and rosea; Vinca alba, and V. rosea; Erica ampullacea, and tribyana; Fuchsia formosa elegans, and Lanei; Citrus Aurantium, and two fine plants of Nerium splendens, gracefully bending under the beautiful trusses of rose-coloured flowers.—Messrs. Pope and Sons also sent a collection of plants, not for competition, containing fine specimens of Cycas revoluta, Cereus lanuginosus and pentagonus, Erica tribyana, ampullacea, and viridiflora; and other plants of equal merit. The following is the list of Prizes:—*Fuchsias.*—1, Exoniensis, Mr. Woodward. *Best Three.*—Lanei, Ballooni, and Conspicua arborea, Mr. Woodward. *Greenhouse Plants.*—1, Agapanthus umbellatus, Mr. Woodward. *Best Three.*—Fuchsia corymbiflora, the Pelargonium named Sylph, and a seedling Calceolaria, Mr. Woodward. *Extra Prizes.*—Nerium splendens, Mr. Woodward.

Ancient Society of York Florists, Sept. 5. (Established prior to 1768)—This was the Dahlia Show, which is the last Meeting for the season. The Prizes were awarded as follows:—*Premier Dahlia*: Mr. Quarton, Standard of Perfection. *Dark Puce, Maroon, or Crimson*: 1, Mr. Quarton; 4, Mr. Edward; 5, Mr. Summers, with Essex Triumph; 2, Mr. Edward, with Sir H. Pottinger; and 3, Mr. Quarton, with Admiral Stopford. *White or Blush*: 1, 4, Mr. Quarton; and 5, Mr. Summers, with Bridesmaid; 2, Mr. Edward, with Beauty of Bucks; and 3, Mr. Edward, with Mrs. James Richardson. *Light or Dark Rose*: 1, Mr. Quarton, with Mrs. Shelley; 2, Mr. Quarton, with Wignall's Queen; 3, 5, Mr. Summers; and 4, Mr. Barrinee, with Mrs. Shelley. *Buff or Orange*: 1, Mr. Edward, with Crantz; 2, Mr. Quarton, with Marquis of Lansdowne; 3, Mr. Edward, with Orange Superb; and 4, 5, Mr. Harrison's Seedling. *Light or Dark Purple*: 1 and 3, Mr. Quarton; 2 and 4, Mr. Edward; and 5, Mr. Harrison, with Standard of Perfection. *Yellow or Sulphur*: 1 and 4, Mr. Quarton; 2, Mr. Edward, with Cox's Defiance; 3, Mr. Summer, with Prince of Wales; and 5, Mr. Harrison's Seedling. *Scarlet*: 1, Mr. Edward, with Cattough's Eclipse; 2, Mr. Quarton, with ditto; 3, Mr. Harrison, with Nonpareil; 4, Mr. Edward, with his No. 13; 5, Mr. Harrison, with Nonpareil. *Light Edged or Tipped*: 1 and 2, Mr. Quarton, with Beauty of Sussex; 3 and 4, Mr. Edward, with Princess Royal; and 5, Mr. Summer, with Princess Royal. *Shade or Bubious*: 1, Mr. Edward, with President of the West; 2, Mr. Quarton, with Girling's Prince of Wales; 3, Mr. Edward, with Madame Charivari; 4, Mr. Quarton, with Rouge et Noir; and 5, Mr. Harrison, with Lord Howden. *Lilac*: 1 and 2, Mr. Quarton, 3 and 4, Mr. Edward, and 5, Mr. Summers, with Miss Abbott. *Seedlings*: Mr. Harrison.

Reviews.

A Descriptive Catalogue of Roses, cultivated for sale by Messrs. Wood & Son. 1844. Taylor.

THIS is another of those descriptive catalogues, the importance of which we last week insisted on. It is divided into two parts, the first including Roses that flower in June and July, the other such as flower from July to November—a very useful variation from the common plans of arrangement, considering how large a part of the wealthy class never see their country residences before the beginning of August. Its orthography has apparently been carefully attended to; but we really abandon all hope of ever ascertaining how the majority of Rose names should be spelt, and therefore cannot blame Messrs. Wood and Son for any errors that have escaped the quick eyes of the reader in Messrs. Taylor's printing office. It is, however, evident that Berlise should be Berlèze, after the writer on Camellias of that name; Casimir Perrier spelt his name, we believe, with one r; Mamoras should certainly be Marmoras; General Kloeber should be Kleber, we presume; and we imagine that for Hypocrate, Columbrieux, and Jean d'Arc, we should read Hippocrate, Colombine, and Jeanne d'Arc. However, these are things that Rose-growers think little about.

The Meteorological Ephemeris for 1845; *with Ruled Pages for Observations.* By Henry Doxat, Esq.

MR. DOXAT makes no pretence to weather prophecy, further than may be gained by a very attentive consideration of those influences which may be naturally supposed to influence atmospheric changes. He was so very nearly right this year in some of his anticipations—for they are neither guesses nor predictions—that we intend to watch his "Ephemeris" carefully next year, and we recommend others to do so likewise.

The Mother's Primer; a Little Child's First Steps in Many Ways. By Mrs. Felix Summerly. 12mo. Longmans.

"MY experience with children," says the Authoress, "is, that learning to read may be a pleasant instead of a painful task." We think so too, and recommend mothers to study, by the help of this pretty little book, how to make it so.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

ALONA CŒLESTIS. Sky-blue Alona. (*Greenhouse Shrub.*) Nolanaceæ. Pentandria Monogynia.—It has long been known to botanists that Chile and Peru abound in shrubby plants allied to Nolana, few of which are yet published, but including among them some species of remarkable beauty. Hitherto our gardens have possessed no others than N. prostrata, tenella, paradoxa, and atriplicifolia, of which the first and last alone remain in cultivation. But they are annuals, and, with the exception of the last, of small importance for the purposes of decoration. The shrubs are still to procure. Of these one species, viz. this one, has at last been raised from some of Mr. Bridges's seeds, by Mr. Best, gr. to A. Park, Esq., of Merton Grove, Surrey. It proves to be a very fine thing, with pale sky-blue flowers, each of which remains in beauty for several days. Its habit is that of a soft leaved Heath, and it appears likely to form a bush of some such size as a common Pelargonium. What its proper treatment may be we are unable to tell, having had no opportunity of studying the plant; but we presume it will thrive with the same cultivation as Scarlet Pelargoniums, and we hope it will prove a capital thing for bedding out during the summer. We would, however, suggest to gardeners, that as all the Nolanas appear to be shore plants, salt in small quantities may be found useful in the soil. A plant of it was exhibited to the Horticultural Society in July last, when it received the silver Knightian Medal.—*Botanical Register.*

Garden Memoranda.

Hewell Hall, near Bromsgrove.—At p. 663 of our volume for last year we gave an amateur's sketch of this interesting place. At the risk of repetition we now offer an account of it by a correspondent of great skill as a gardener. Our readers may be anxious to compare the views of two different persons concerning the same array of facts. Hewell Hall is situated in one of the finest parks in England. The mansion is a noble Grecian building, placed in the very worst situation in the whole park. One cannot help admiring the princely liberality that suggested the idea of such a pile, and pause to condemn the taste that could place it in such a situation, and in such a park too! Few demesnes afford so much choice in the site of the mansion as this, having such a diversified surface, and grouped in all directions with huge masses of stately timber. An extensive lake has also been formed near the house, certainly in the best situation for such an ornament. The outline, however, wants boldness and variety; for although conceived on a scale commensurate with the magnitude of the place, it is nevertheless destitute of interest from its inartistical form. This is very strikingly exemplified in the opposite shore running nearly parallel with the mansion: and as the latter does not occupy an elevated situation, the defect becomes more apparent and objectionable. The splendid groups of timber trees which meet the eye in all directions, are, in most instances, judiciously placed. They are composed, however, of trees assimilating greatly in form, and want the Cedar of Lebanon, and in some instances the Lombardy Poplar, to give variety and style to the general character. The

lawn near the mansion can boast of one of the finest pieces of turf in this country; it is the very perfection of what turf should be—quite free from Moss and Plantain, and as smooth as a billiard-table. On this lawn are large masses of shrubs, herbaceous plants, and gay annuals, mixed together and surrounded with a kind of wicker-work, which gives an idea of their being huge baskets of evergreens and flowers. For ourselves we should prefer to see the branches of the Portugal Laurels and other evergreens resting quite unobstructed on the beautiful sward, and the wicker-work inclosing lesser-sized clumps, judiciously distributed, and filled with Scarlet Pelargoniums, Salvias, &c. &c. On this lawn are two very fine Pinus cembra; near it, and connected with the house, is a Dutch garden on a small scale. The walks from this lead to a range of conservatories, filled with plants in the highest health and culture. Mr. Markham pointed out some Camellias to us of an immense size, which he had transplanted in consequence of the alteration and re-erection of these houses; they had not, apparently, received the least check—indeed, nothing could surpass the health and vigour of these truly magnificent specimens. Near this is a rock-garden, formed out of a gravel pit. This is one of the few things of the kind we can bear to look upon. It is a pity, however, that geometrical forms should have been admitted in the arrangement; they are most certainly out of place here; the basins of water for aquatics are raised above the surrounding walks and beds, which should never be in any case; the beds also were rendered too gay with Scarlet Verbenas. The mind in such a scene reverts to those plants we find in rocky wilds and alpine regions, and this feeling should not only be created, but maintained with scrupulous severity. The water in the basins was as pure as crystal—no trifling matter, in our estimation, when water is introduced in garden scenery. How often do we find these receptacles for plants foetid pools, covered with Duckweed, and swarming with frogs and tadpoles! We observed the walks leading to this garden, and in places where the trees overhang them, edged with a kind of tile. Edgings of this kind are admissible in geometrical gardens of some kinds, but they do not associate well with rural scenery. When the shrubs are not surrounded with turf we should prefer edgings of Ivy, which answers admirably, and would harmonise well with the beauty and character of such a situation. The French garden, as it is styled, is upon an extensive scale, and designed with great judgment and skill. It is just now looking brilliant, from there being an immense display of all kinds of profuse-blooming plants, well arranged and superbly managed. An improvement could readily be effected in this garden by the introduction and right disposition of fastigiate evergreens flanking the broad walks of turf and gravel; such, for example, as the Irish Yew, Cypress, Juniperus excelsa, Cupressus thurifera, Cupressus torulosa, &c., &c. At some distance from the house, in an outer park, is the kitchen garden, which is equally well managed; the fruit trees of every kind are loaded with fruit; the Peach and Nectarine trees against the open walls were quite free from red spider. The kitchen-garden crops were in luxuriant health, evincing none of the signs or effects of this dry season. The Pine-apple, the Grape, the Peach, and the Fig, are here all cultivated in the highest possible perfection; indeed, it would be difficult to point out another place where these are all equally well done. The Pines are chiefly grown in pits, heated by hot-water gutters; the gutters were formed of zinc, but this kind of metal has proved a failure, and Mr. Markham is about introducing Burbidge and Healy's cast-iron gutters, being perfectly satisfied that this is the most efficient mode of obtaining bottom-heat. Mr. Markham has been long celebrated for his superior management of the Grape-vine, and we trust he will, through the medium of the *Gardeners' Chronicle*, favour his less fortunate brethren with his system of culture. The writer of this article has had several opportunities of witnessing the extraordinary success, during the last ten years, attending the culture of the Vine at Hewell, and he can safely aver that he has never seen anything equal to it in Great Britain. It is almost unnecessary to repeat that the whole of these extensive gardens and grounds were in the highest possible keeping; the same order prevails, from the rubbish yard to the lawn and conservatories. The whole of the turf looked as if it had all been mown that morning—the walks all swept, and the whole of the surface of the ground, whether in the flower or kitchen gardens, just stirred and raked. Our attention was directed by Mr. Markham to a most important circumstance, which would have drawn on the incredulity of Mr. Knight himself. That celebrated physiologist considered the Golden Pippin Apple to be in the last stage of decay. Here, however, it is in its youth, growing as vigorously as any Apple in the garden, both old and young trees producing fruit abundantly, without in either the least signs or indication of progressive decline. This doctrine of the deterioration and degeneracy of some of our best old Apples, is unquestionably opposed to analogy in trees generally; and although this instance is somewhat remarkable, it at least leaves the question open for further investigation.—*R. G.*

Miscellaneous.

To Cook Tomatoes.—Take a ripe Tomato, quite red, but not soft. Cut out the stalk and scoop out the seeds, leaving as much of the flesh as possible. Fill the inside with forcemeat (which will be better if mixed with a little chopped ham or tongue). When well-stuffed set it in a Dutch oven, in a dish, before the fire, with a piece of butter on the top of the Tomato, and leave it to roast till brown. Care must be taken that it does not burn.

New Discoveries concerning the Pollen of Plants.—Mr. Siegfried Reisseg announces that he has discovered that pollen will produce its tubes in the parenchyma of the stem and leaves, as for instance, that of an Allium in Potato tubers; that it then grows into conferva-like cellular green plantlets; and that pollen will change, under certain circumstances, into animalcules, such as those of Ehrenberg's genus Astasia! What next?

The Jay.—Having the reputation of being partial to the eggs of young birds is quite enough to include this beautiful bird in the list of destructives; its principal food, however, being Acorns and Beech-mast. This terminates, it is believed, those birds that come under the gamekeeper's denomination of "varmint." The rook has been omitted, as it is believed that farmers have now become sensible of the advantages they confer; and instances are known that where, in their ignorance of the utility of the rook in clearing their lands of grubs, &c., they have prevailed on their landlord in getting the rookery destroyed, in a very short time, finding out their error, they have earnestly entreated for its restoration. Still the eye is too frequently disgusted in seeing one of these birds suspended in the field, under the idea of saving a few miserable potatoes, &c. &c. The gardener's list is rather more numerous; it will not be necessary to enumerate all which come under his ban. If the money spent in powder, pay of boys kept from school, and the original cost of the gun, were expended in teaching net-making to those in the parish who are lame, or otherwise infirm, a saving would be obtained, and a moral benefit conferred. Too much praise cannot be awarded to the benevolent exertions of the late Rev. Charles Bathurst, for introducing this art into his parish, superintending it personally, and for the little volume which records his proceedings, with the mysteries of the art of reticulation.*—*J. M.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

After the stove has been kept dry for some time, as is always done more or less from the end of August, the red spider makes its appearance in some collections, in greater numbers than at other times. This is the worst time in the year to permit the ravages of this insect, as if the foliage is now disfigured it must remain an eyesore till next season's growth; therefore on the first appearance of this evil, apply sulphur to the pipes, &c.; and any plants more liable to the attack may now have their winter pruning, rather than be a harvest for the red spider. See that Gloxinias are well ripened before they are set to rest, and likewise that a proper label is fixed to all those kinds which rest periodically. All woody plants ought now to be done growing in the stove; slight fires may be made in the morning; the watering got over early in the day, and a free current of air admitted on all fine days for a few hours.

Conservatory.—Plants in this house, the greatest portion of which are expected to be in flower, may be kept as still as if they were in a Ward's case from this time till the beginning of the growing season; merely giving air to keep down sun-heat occasionally; indeed, sun heat will do no harm from this time, although it should raise the temperature up to 70° or 80° for a few hours, as the excitability of plants is now over. Plants thus treated will get over the winter much easier than where the ventilators are in requisition at every change of our variable climate, as was the case in my younger days; but we affect that unless your plants, pots, borders, walls, trellises, &c. be kept as clean as a drawing-room, this system will not answer with you, as the effluvia rising from decaying leaves, ill-drained pots, and mossy borders, will soon contaminate the confined air, and you must have recourse to constant ventilation, as in the olden times.

Greenhouse, Pits, Frames, &c.—There is no plant, however hardy it may be, that will endure with impunity the drenching rains of autumn, if planted in a pot. An Oak, Ash, or Elm might thus be injured in wet seasons; how much, then, must half-hardy plants endure if exposed to the wet! And yet it is no less injurious for them to be housed early; that is, after they have passed the nursery stages. All young and delicate plants, such as Heaths, &c. should now be put into frames, not through fear of cold, but to guard them from the frosts and heavy dews; and all large and more hardy sorts should now be placed in the full sun on the south side of hedges, walls, or other screens, and some means of throwing off the wet from them devised. Cinerarias, Chinese Primroses, Calceolarias, and the like, which have been grown on north or shady aspects, should now be changed to face the south. Sufficient quantities of peat, loam, sand, and leaf-mould in a dry state, for winter and early spring potting, should be put under cover at any time now, when they are in a dry state. Our success or failure depends on the state and condition of our compost more than many are aware of.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

We have few finer tribes of plants for bedding out in the summer season than the Petunia, and few genera in which a greater improvement has been effected as to the quality of the flower. One of the finest varieties of the purple class for forming groups is undoubtedly Violacea superba, a variety sent out some years back by the Horticultural Society, and which has the property of holding its colours until the flowers are quite withered. Prince Albert is another variety possessing nearly the same properties, with a little improvement in form; and Duncan's seedling Elegans with a white throat, Beauty, Gem, Newmanii, and Newmanii superba, are flowers of nearly the same colour (purple), the last four are of unusually large size. The great disadvantage of the last four is the looseness of the flowers, and their tendency to burn or lose their colour under bright sunlight. Lady Peel has the same fault, and though a remarkably free bloomer must be discarded in consequence. Of the pale colours some five varieties have this season been sent out; a very distinct sort is Ivery's Pet, a small flower, not much larger than a Nierembergia, with a pale ground, the throat pencilled with dark purple, and the edge of the flower beautifully mottled with dark-rose. Magna Charta is a larger flower of the same character, the mottling being distributed over a broader surface; and this mottling is not the result of decay, as is the case with "Miller's Punctata," but is the natural and proper colour of the flower. Reliance has a finely pencilled throat, on a ground of very pale lilac, and slightly edged with purple. Kentish Beauty has a very dark pencilled throat, on a deep lilac ground; and Enchantress has the same character of throat on a rich peach-blossom surface. Ovid is a large flower of superior form, and of a deep purplish-lilac colour. Triumphans, or Rosea alba, has a white flower edged with deep rose. Erubescens is an old but an abundant flowering kind, of a pale lilac colour; and Lady Sale has very delicate pale lilac flowers slightly edged with pale rose. These are the only varieties which a careful examination of the best metropolitan collections has enabled me to recommend as distinct. They may all be propagated by cuttings, which root freely in a gentle heat; but as they are liable to become long-legged, spring propagated plants are preferable for bedding out.

Reserve Garden.—The sowing of Annuals to stand the winter must not be delayed; a light free soil is the most suitable, but it is not desirable to have them in a very sheltered situation. At this place we find them to stand the best when the seeds are scattered over the rockwork.

Bulbs.—Where these are required to be got in for the flower-garden in the spring, no time should be lost in making a selection of them, and it is worth remarking that good bulbs, though they may cost a little more, are very preferable to going to a cheap market and getting indifferent kinds.—*W. R. A.*

III.—FLORISTS' FLOWERS.

Carnations.—As we have before insisted, parties desirous of having layers which will healthily pass through the coming winter, will do well to pot them off as soon as rooted; and where new and fresh varieties are required, the best plan is to see them taken off. Should layers come from a distance, examine that part of the stem which communicated with the parent plant—it will sometimes have a cankered or decayed appearance; this must be carefully removed with a sharp knife, and the stem cut back to where it is healthy. Should there be no appearance of decay the stem must then be cut across at the joint, which will frequently emit fresh roots. As the layers are taken off, the compost in which they have been grown may be turned into the Tulip-bed, either as a substitute for that which previously formed the bed, or to ameliorate that which is already there.

Pinks.—It is now a good time to plant out those intended for flowering on the best bed next year. By putting them out at this season there is a much greater certainty of their coming or blooming in true character next season. Headley's Duke of Northumberland, Norman's Splendid, Beauty of Weston, Kirtland's Gay Lad, Bunkell's Queen Victoria, and Wilmer's Miss Jones, are worth adding to collections, lacing well and being all "rose-leaved," or nearly so. *Tulips.*—Prepare a bed for offsets; they ought to be in the ground at least a month before the main bulbs are planted. Continue to turn the soil of the best bed at intervals, giving it the benefit of sun and air. *Auriculas.*—Take care to have the frames intended for the reception of these plants properly cleaned, and the broken squares of glass repaired, &c.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Pines showing fruit after this time, although they cannot be expected to produce as fine fruit as if earlier in the season, will yet be found very useful, and should have every encouragement given them, while the season still continues favourable. The warmest situation in the house should be allotted to them, and when dry they should have a little liquid manure, for the next three or four weeks. Plants that appear likely to show about November or December, if kept at a temperature of 60° or 70°, should have the heat lowered gradually to 60° by night, and 70° by day, which would be just sufficient to keep them from standing still, and would retard their coming up. After the season begins to turn there is a much better chance of swelling off fine fruit. Begin now to lower the temperature for the younger successions, letting the decrease be very gradual. Do not let them want for water, but continue to look them over twice a week, lest any of the plants near the pipes or flues should become too dry. Plant all suckers as soon as taken from the plants, as they soon shrivel by laying out, and are consequently much weakened.

Vineries.—If damp is kept from the late vineries, the damaged berries cut off the bunches, and the ingress of wasps prevented, little else will require attention for some weeks. Where there are not many vineries to protect from wasps, a cheap way is to make bags of tissue paper, to draw up over the bunches, wetting the mouth of the bag round the stalk. If this is carefully performed the bloom need not be injured. I like these bags—they are a cheap, simple, and effectual prevention from insects and dust. Prune the Vines as soon as the leaves fade, and let them be thoroughly cleaned from dust and insects. When this is done let all alterations, repairs, whitewashing, and painting be done, when the houses may be used as greenhouses, till required for forcing. Continue to stop all laterals in the late houses.

Peach House.—If any fresh trees are to be removed from the walls to the Peach-house, the sooner it is done now the better, as the shifting will check the present season's growth, and the wood will ripen sooner. The tree will make new roots enough this autumn and winter to enable it to produce a good crop next season if of sufficient age. In preparing the place in the Peach-house, remove all the old soil that can be taken away without material injury to the other trees in the house, and fill up with fresh deavesd turfy loam, rather poor than of any posture. No manure need be used. Keep the tree high to allow for sinking, and give a good watering to settle the soil round the roots. Continue to prune the trees in the late houses, if the leaves are not gone.

Fig House.—Figs in tubs and pots, still bearing, should be assisted with liquid manure when dry; but in less quantities at a time as the power of the sun declines. It is not well to give much water to the Fig borders now, as the trees should be induced to ripen and go to rest early.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Peach Trees.—In paying attention to the fruit at this season do not let the trees be forgotten, but take every opportunity for hastening the maturing of the wood. The points of the shoots might now be shortened, and the large leaves on strong shoots cut through the middle. The shortening the shoots will cause the buds left to swell better, and unless the trees receive too much moisture at the roots there will be no danger of the buds then bursting. In extreme cases of luxuriance the stronger roots might be pruned with advantage.—*Wasps* are now getting extremely troublesome, after we began to think ourselves secure from their ravages. Every means must be resorted to to keep them in check, by covering with gauze, &c., but even then they will often discover a cranny by which they may enter. For fine single fruit nothing is better than wrapping them round thinly with wool, or cotton wadding; and Grapes that are worth preserving should be bagged at once.

Tomatoes will now require considerable attention to get the fruit well ripened, by stopping the shoots, and cutting off the leaves very liberally, so as to expose the fruit fully to the sun. *Onions* should now be dried and got off the ground as soon as possible; and the ground well dug, with the addition of a little dung, will make a suitable place for the main plantation of Spring Cabbages, which had better be got in without much further delay. The last crop of Autumn-sown Onions, and the last sowing of Lettuces may also now be made. *Small Salads.*—We have seldom alluded to these, as where they are in demand, the sowing of them is a weekly occurrence. Normandy and American Cress may now be sown for the Winter. *Kidney Beans.*—A quantity of the Early Dun, Cream-coloured, or Speckled Dwarf China, may be sown in pots in a warm place, to perfect their produce under the protection of a frame or pit afterwards. No more need be sown, where the plants cannot have the advantage of fire-heat. *Mushroom-house.*—There is little difficulty in procuring Mushrooms after this period, until May next season, in houses where a sufficiency of heat can be commanded by artificial means; such as thick covering, fermenting material inside the house, or flue or hot-water pipes. If in a house with shelves, upon the Oldacre system, the depth of the bed must be regulated by the quantity of materials at your command, and the period you expect them to produce. A bed of 3 or 5 inches thickness of dung may be en-

* "Notes on Nets."

pected to produce for six weeks; and, as I am scarce of material, as soon as a bed finishes bearing profusely, the top part is removed, fresh droppings added to the depth of two other inches, the old and the new mixed together, spawned, and earthed at the proper time—the same as in a fresh bed. It is not of much consequence whether the material of the bed is rather dry or rather wet; only in the first case, after spawning, a covering of wet cow or horse-dung is added, and in the second case, the spawn should be wrapped in a handful of dry litter before being inserted. In all shallow beds, the earth should be put on after spawning as soon as the state of the bed will permit, regulating the thickness of the earth from 1 to 2½ inches, according to the thickness of the bed, and the time you expect them to produce; as, the thinner your covering of earth, the sooner will you obtain Mushrooms,—at the expense, in general, of solidity in the Mushroom, and permanence in the crop. Both with in-door and out-door beds the heat should be rather on the decline, and just about milk-warm, before spawning; and then if, after earthing-up, the heat should not be sufficient, you may throw what you wish into the bed by covering. Before you could remedy too much heat, the spawn is worthless.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Proceed with preparations for fresh planting, if any is to be done during the ensuing season, by clearing the ground of any useless shrubs, such as Briars, Thorns, Furze, &c. Trench and hole the ground where any additions are to be made.

Coppice.—Refer to last week's *Chronicle*, and attend to what is wanted to be done at this season. Remove any useless stuff, where something more profitable may be substituted.

Young Plantations.—Attend to former directions. Too much attention cannot well be paid to these where it is wished to have them profitable, as well as creditable to the owner and to the person intrusted with the management of them.

Hedge rows.—Make ready for fresh planting, if required. Filling up the places where trees have died should be proceeded with at every opportunity.

Nursery Work.—The most important work at this time is eradicating all weeds as they appear—they make great progress in a little time at this season. Train the leading shoots of the plants until they have done growing for the season, and pinch off the ends of the strongest side-shoots that extend too far from the stem.—*W. B.*

VII.—COTTAGERS' GARDENS.

The principal operations to which attention is now to be directed are the protecting of Grapes and the gathering of fruit. The Grapes, which should now be swelling fast, had better be put into small gauze bags, to preserve them from the attacks of wasps, &c., which are now troublesome. With regard to the gathering of fruit, such as Apples and Pears—the sorts that Cottagers generally cultivate—great care is necessary to keep them from being bruised. They should be handled like eggs, in order to insure their keeping. The time when the fruit is ready for gathering is indicated by its beginning to drop of its own accord from the trees, by its parting freely from the stem on being slightly moved, or if, on cutting open one of the fruit, the seeds are of a dark-brown colour, it is fit for gathering. In performing this operation, however, the fruit should never be shaken from the trees, as is often done, but it should be all hand-picked on a dry day. In storing it, let it be taken from the basket, and placed where it is to remain with great care; and, if possible, let it be arranged side by side, and not placed one upon another. With respect to Vegetables, look over the seed-beds, and keep them clear of weeds. Onions, if not already done, should now be dried and stored as soon as possible, in order that the ground may be got ready for other crops. Owing to the late favourable weather, the flower-borders still maintain much of their beauty. Scarlet Pelargoniums are in fine condition; and I have lately seen in the open ground some noble bushes of Fuchsia Riccartonii in luxuriant health, and loaded with blossoms. This is an excellent border variety; it is a very profuse bloomer, and may be easily kept over winter by covering the root with a little litter or leaf-mould, so as to keep out frost. Herbaceous plants that are done flowering should be cut down, and have their stems removed whenever they become unsightly. Dahlias, on the contrary, that are still in fine bloom should be trimmed and tied up. If the ground is weedy, run the hoe through it, and endeavour to keep the whole as neat and clean as possible.—*J. M'H.*

State of the Weather near London for the week ending Sept 19, 1844, as observed at the Horticultural Garden, Chiswick.

Notices to Correspondents.

ASPARAGUS.—*A Subscriber.*—Consult a letter from Mr. Bree in to-day's Paper.

BRAZILIAN BEET.—*Toby.*—We shall be much obliged.‡

BULBS.—*Flora.*—Grow the hardy bulbs in a good peat border, in which there is a tolerable proportion of loam. All the tender ones must be planted in loam and kept from too much sunshine, in a well-ventilated greenhouse. We cannot go into details, for each of your 40 sorts would require a separate set of directions, for which we have no room; nor indeed can we undertake to answer such a crowd of questions.

CANKER.—*R., Clapham.*—There is no known remedy for canker in Apple trees. Some varieties are more subject to it than others, and in some soils it is induced on every variety planted in them. Wood that is produced in wet cold seasons is apt to canker in succeeding years. If it is owing to the variety, this may be changed; if the soil is the cause, endeavours must be made to better it. Lime will probably do good. Shoots produced in a bad summer should be well shortened in, and the diseased parts of the old branches should be cut out. Your method of numbering Labels is the old well known plan.‡

CARNATIONS.—You will find lists of Carnations in No. 9, p. 136, and in No. 38, p. 589, of the present year, from which you can select the number you require; and a list of Polyanthus also, No. 9, p. 136.*

COPPICE SHOW.—*C. W., York.*—The Judges at this Show placed several seedlings which, owing to informality on the part of the exhibitor, did not receive a prize. We especially noticed a scarlet bizarre, a noble striking flower; it had, however, a very slight serrature on the edge of the petals, but we should say it is better than two-thirds of the varieties comprising that class. The scarlet flake was also fine; white, good, high coloured, and the petals of good texture and well ribboned. A purple flake, we understood a seedling from Ely's Mango, had all the good properties of that esteemed flower, with a darker stripe. *W.*

CINERARIAS.—*C. K.*—You will find an excellent variety in the following 12 sorts, viz.: Eclipse, Rival King, Victoria Regina, Triumph, Goodeii, Emperor, Red Rover, Black Knight, Fanny Elsler, Captivation, Compacta, and Criterion.*

CYPRIPEDIUMS.—*A. H.*—We believe the secret of keeping these in health is to preserve them during winter in a frame whence frost and wet are excluded. They like peat. Upon the management of the bee and spider Ophrys we regret to say we have no information. Perhaps some correspondent has.

EVERGREENS.—*C. R. D.*—Cut down your bushes in the beginning of April; and serve them all alike.

FRUIT.—*J. B.*—The maturity of fruit is influenced by so many different circumstances, such as soil, elevation, aspect, and latitude, that every one must be his own adviser on that point. To give weekly directions would only mislead.

FUCHSIAS.—*M.M.G., F.H.S.*—Procure the following 12 sorts: F. Exoniensis, Formosa elegans, Epp's Kentish Bride, Smith's Vesta, Robusta, Bell's Queen, Conspicua arborea, Pride of Peckham, Youell's Queen Victoria and Countess Tyrconnel, Halley's Sanguinea, and Standish's Candidate.*

HEATING.—*T. E F.*—The circulation of water is the same, whether the flow-pipe is quite full or not.——*A Subscriber.*—You are right in having plenty of water: we cannot, however, recommend you to construct your hot-water tank of bricks and cement; for it is found in practice almost impossible to prevent the joints breaking, in consequence of expansion and contraction; unless, indeed, the tanks are constantly filled with hot water, in which case they will probably stand. By all means have some pipes in addition, and manage, by means of a stop-cock, to heat them or not, as you please. A second-sized boiler will do.

HERBACEOUS PLANTS.—*O. G.*—The following are 12 handsome and rather new hardy sorts:—1, Aquilegia fragrans; 2, Statice pseudo-armeria; 3, Campanula grandis; 4, Cynoglossum longiflorum; 5, Sedum Sieboldii; 6, Epimedium macranthum; 7, Hotela japonica; 8, Phlox Van Houttei; 9, Salvia hians; 10, Potentilla insignis; 11, Pentstemon crassifolium; and 12, Anemone vitifolia.¶

HORTICULTURAL SOCIETY.—*An Exhibitor.*—We cannot insert letters at a moment's notice; yours will appear next week.

INSECTS.—*S. A. S.*—There is a Clover weevil, but we should feel obliged by your sending Mr. Curtis some of the injured leaves and specimens of the insects alive with them in a small box.*R.*——*N. Esk.*—If you will favour Mr. Curtis with a portion of a Melon-leaf and some of the leaping insects, in a box protected from pressure, your queries will be attended to; but the leaf was so dry and matted together that it was impossible to find anything. He would also like to see the insects injuring the Calceolarias.——*T.*—The destructive grubs you sent are the offspring of a moth called Noctua exclamationis, whose history is given in our columns of this day. *R.*——*C. J.*—Your caterpillar, it is expected, will produce a Saw-fly, called Trichiosoma Lucorum, but in future we beg that with inquiries you will favour us with specimens. *R.*——*W. H. R.*—From your interesting letter we are inclined to believe that your Wasp's nest is the work of Vespa Britannica, vide "Curtis's Brit. Ent.," *vol.* 760. Mr. Gray, of the British Museum, will inform you if the specimen would be acceptable. *R.*——*John Cat.*—Your beautiful larva is the Privet caterpillar, and will produce Sphynx Ligustri. *R.*——*J. M.*—One of your insects is the young larva of a Lady-bird, lately figured and described in this Journal; the other is too much injured to decide upon its name. It may be the larva of a small moth. We cannot advise you how to exterminate the Rose maggots, but if our correspondents will furnish us with sufficient materials in the spring, we will turn our attention to the subject. *R.*——*C. B.*—It is generally impossible to give advice regarding Melon plants, for without examining them we are often unable to ascertain whether the mischief arises from atmosphere or insects. *R.*——*Q. Q. Q.*—The caterpillar last sent will change to a moth, called Spilosoma lubricipeda, figured and described in the 1st vol. of the *Gardeners' Chronicle*, p. 700. *R.*

LAVENDER.—*A Subscriber.*—If your ground is in readiness, and plants at hand, they may be put in with advantage now. The distance between the rows should be two feet, and the plants in the row should stand about one foot apart. If, however, the ground is not in readiness, you had better defer planting till spring. The soil in that event, if wet, should now be well drained, and laid up in ridges to be exposed to the action of the weather, until about the end of March or beginning of April, when the ridges may be levelled down, some well decayed manure dug in, and the Lavender planted. The best plants are those raised from seeds. It likes a light dry soil.‡

NAMES OF FRUITS.—*Tyro.*—Your Cherry, called the August Heart, has not been found under any other name. Some Correspondent will probably afford information regarding its locality, and where plants of it may be obtained.‖——*J. W.*—Black Morocco Grape.‖——*C. C.*—1 and 3, Hawthornden; 2, Old English Codlin; 4, Pomme de Neige. Plums, 1, Diamond; 2, Coe's Golden Drop; 3, Blue Imperatrice. Pears: 1 and 3, Jargonelle; 2, Beurré de Capiaumont, of some, but not the true one.‖——*G. B.*—1, 2, 4, 9, Royal George; 5, 8, Grosse Mignonne; 6, Red Magdalen (of Miller); the Nectarine, No. 3, is the Elruge. The specimens were fine.‖——*H. W. B.*—No. 1, Yellow Ingestrie; 2, Summer Pearmain (of some); 3, Court of Wick; 4, Ribston Pippin.‖——*R. M. K.*—No. 1, Henri the Fourth Pear. Plums: 2, Purple Gage; 3, Winesour; 4, bruised—probably the Nectarine Plum. Apple: Beauty of Kent.‖

NAMES OF PLANTS.—*F. J. Z.*—Apparently Cuscuta chilensis, which will soon strangle everything that comes in its way.——*J. C.*—Your fragments seem to belong to Kutoca viscida.

PELARGONIUMS.—*J. R.*—To your collection you may add the following:—viz.: Sultana, Lord Chancellor, Luna, Queen Phillipa, Hodge's Oberon, Beck's Susanna, Unit, Hoyle's Titus, and Pompey, and Lyne's Imogene. A very few of your sorts may be discarded; these will suggest themselves. Some of the high-coloured varieties, although not good in shape, are useful in adding splendour to the general effect, and should be kept till others are produced of the same colour, with finer properties. The list of flowers in your postscript we cannot recommend, as your taste lies in an opposite direction. The growers' lists not being all published, we may have to add to the above list.*

PETUNIA.—*M. M. G.*—A variety named Medora, Calceolarias are so numerous that it is impossible to answer your question.*

PLANTS AND TREES.—*J. M. S.*—The following trees and shrubs are suitable for planting on an elevated situation near the sea, in the south of Devon:—Leycesteria formosa, Fuchsia arborea, bella, and cunninghamii; Hydrangea hortensis, Arbutus procera and others; Berberis aquifolium and darwinii; Alnus cordata, Quercus cerris, Fulham, Rex, coccinea, and ambigua; Ulmus vegeta, rubra, nigra, and stricta; Crataegus Douglasii, orientalis, prunifolia, and Aronia; Garrya elliptica, Rhipophae conferta, Cytisus elpinus; Magnolia grandiflora and conspicua; Pinus pinaster, insignis, and pinea; Abies declara and canadensis; Arundo donax, Allantus glandulosa, Syringa persica, and the common Lilac.¶

ROSES.—*A. P. B.*—Any of the great Rose-growers will tell you, better than we can, what are the best Roses to grow for competition. You had better send your order to them with no other directions except as to the climate they have to be exposed to.

SEEDLINGS.—*J. N. C.*—Your double Canterbury Bell has nothing remarkable about it.——*A. C.*—Your seedlings are between Achimenes, Specs and species; they are pretty, but not very distinct, and we do not attach importance to them.——*J. D.*—Your Achimenes is too much like cotechea; it would not improve much by having a larger pot.

STRAWBERRIES.—*G.*—Give your Strawberries a good top-dressing of guano, mixed with six times its bulk of light soil, in the end of February. If good it is suitable to them.

THE VINE.—*N. B.*—There is no good or even tolerable analysis of this plant. The nearest approximations to a good one are those of Geiger and Proust, but they are vague and incomplete.

THUNBERGIAS.—*O.*—These are stove plants, and do not succeed well in a greenhouse. If they are not grown in a warm moist atmosphere, they either become stunted or are attacked by red-spider.¶

TOBACCO.—*Alpha.*—In order to cure Tobacco, so as to render it most effectual for the destruction of insects, it is not sufficient that the leaves be taken off and merely dried like specimens. Liebig states, that in the process of curing, the addition of water is necessary for the formation of that peculiar oil to which the virtue of the article is attributable. He also mentions fermentation; but if this be at all allowed, it must be in an extremely slight degree, otherwise the article is materially wasted in quantity, whilst the quality is rendered decidedly bad. When mature, the leaves slightly yellow, pull up your plants, or cut them very close by the roots; hang them by the root end in a dry place, without stripping off the leaves. In a day or two they will occupy less space, and should then be kept in a heat of 70° or 80°, till even the midribs of the leaves are dried up, and the leaves in the state in which they would easily crumble to snuff. They are very absorbent, and by wetting the floor and otherwise damping the situation very much, the leaves will soon acquire the quantity of water absolutely necessary for the oily formation above alluded to. After several days, drying may be again commenced, and continued till such time as the leaves are considerably dried, yet still retaining sufficient pliability to admit of their being stripped from the stems without breaking. They should then be spread out flat above each other, in handfuls, pressed, then finally well dried, and packed up close till required for use. Thus managed, you will find it superior in quality to much of the imported Tobacco, for the destruction of insects on wall trees, &c. It is impossible to say how much of the imported Tobacco is rendered inferior, of a burned foxy colour, in consequence of improper fermentation, and of water not being supplied during the process of curing.‖

TULIPS.—*N. N. P.*—Three Bizarres: Polyphemus, Charbonier Noir, and Catafalque. There is no method of getting a speedy increase of bulbs. There are no plates of these flowers.*

VINES.—*A. B.*—As soon as the Fruit is cut you may remove as much of the old wood as will admit sufficient air and light for the maturity of the young wood.‖

WASPS.—*L. Short.*—If you know of a better way of destroying these creatures than by turpentine, pray say what it is. We doubt the possibility of anything being more effectual. But why do at three different times what may be done so easily at once?

MISCELLANEOUS.—*X. A.*—Achimenes longiflora cannot be grown to any good purpose in an open border. You cannot make a fountain without a head of water or some good mechanical contrivance for producing the requisite pressure. The little self-acting fountains are the most childish things imaginable. A heavy rain extinguishes them.——*Omega.*—The ordinary allowance of labour is a man to an acre. For what is called a single-handed place, you may get a man for a guinea a week. Sashes for frames are usually 3 feet 9 inches broad, and 6 feet long. If your pits are sunk they will be more easily kept warm; but then, if the soil is not well drained they are apt to be damp. By all means heat them with some sort of apparatus; of which the sort will depend upon the purpose to which you mean to apply them. You will find many statements respecting that subject in our previous Numbers. Glaze with sheet glass; it is rather expensive, but much the cheapest.——*M. M. G.*—For the pronunciation of Dahlia refer to vol. ii. p. 737.*——*D. J.*—If your object is to procure double flowers, rid your bed of the single ones.*——*N. N. P.*—Double Pansies are not worth cultivating.*——*A. G.* is answered in another column.‡——*A. C.*—We have not received the parcel you mention.‡

SEEDLING FLOWERS.

DAHLIAS.—*F. and A. S.*—Your seedling *Lady Sale* is a promising flower—a bright-yellow regularly tipped with crimson; it is novel in colour and good in form. The centre is well up, but the bloom sent was too young to judge whether this part of the flower developes itself sufficiently.*

FUCHSIAS.—*T. F.*—Your seedling is an elegantly-formed flower, with fine violet corolla, but it differs too slightly from other varieties in cultivation.*——*J. M.*—Your seedlings were not only bruised and damaged by their journey, but the labels were all torn from the flowers, so that it is impossible to determine to which they belong; some of the light-coloured varieties are very pretty, but they are very much discoloured, from being so much bruised.*——*Anon.*—Three seedlings, which are fair flowers, but not possessing novelty sufficient to send out. No. 2, which is the best, is disfigured by having very long and narrow sepals; in other respects it is good, as the tube and sepals are of a transparent and delicate pink, with a deep vermillion corolla: 3 too much resembles others in cultivation; and No. 1, which is a good stout flower, has the same fault.*——*A Kentish Florist.*—Your four seedlings are all good flowers, but they too much resemble each other; 3 and 4 have slightly the advantage, being the brightest and most distinct, and having also the best-formed corollas.*——*J. N. C.*—Nos. 1 and 4 are large, rich-coloured flowers, but the sepals of both are coarse. No. 3 is pretty, but none of them are equal to sorts in cultivation.*

PETUNIAS.—*J. A.*—The best flower among the Seedlings sent is No. 2; light lavender, with dark purple veins; 1 and 3 are common and colourless; 4 is a very fine colour, but too small.*

VERBENAS.—*W. G.*—Your seedling is a good flower, colour crimson maroon, and though it strongly resembles some of the varieties out, from its size and manner of opening, it is equal to any of the same colour.*

PANSIES.—*J—n.*—It is impossible to tell the merits of a flower when sent folded up in paper; it becomes dry and discoloured by the time it reaches us. The centre appears to want distinctness, and the petals substance.*——*A Subscriber.*—No. 22 is a very pretty flower in its young state, fine in form and good in substance; but when fully expanded the margin round the side petals becomes weak and watery, especially in the upper part, where it unites with the ground colour; the eye is also insufficiently marked on the side petals, which shows more in the larger flower. It is a flower of fine form, but deficient in the points we have mentioned. 5 is not so fine in form as 22, but it is of good substance, flat, clean, and good in colour, with a very fine eye.*

PICOTEES.—*Lelièvres.*—Your seedling is pretty in colour, but the petals are too small in size and few in number.*

VERBENAS.—*W. M.*—No. 1 was too much decayed to judge of the true colour of the flower could not be seen; the pink variety, No. 149, is of a beautiful tint, clear, and lively.*

SEED-WHEAT. — Any one desirous of obtaining Seed-Wheat for use this autumn, may ascertain, by application to me, the particulars of the crops of two excellent varieties—Shirreff's Hopetoun, and Morton's Red-Straw White, which have been grown on
WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE,
during the last 3 years. This year's crop is on sale at 8s. a bushel.
—JOHN MORTON, Whitfield.

TO AGRICULTURISTS.

CAMPBELL'S CORN STEEPS.—The Material for Wheat is on Sale by the undermentioned Agents, at 2s. 6d. per gallon.

Notwithstanding the extreme drought of the last spring and summer, the results of the experiments, in very many instances, have been surprising, averaging a saving on seed, in the first instance, of 3s. per acre, and yielding a produce of 20 per cent. additional in straw, and 40 per cent. in grain. Had the season been more moist the result would have been at least double.

From Report of the Judges, Glasgow Cattle Show, Aug. 7, 1844.

"Among the remaining articles of the Exhibition (of Roots, Seeds, &c.), the Judges would direct attention to a series of specimens exhibited by Mr. James Campbell, of Dundee, consisting of various Grasses (they were Wheat, Barley, Naked Barley, and Oats), raised from Seed steeped in a Fertilising Liquid. These were contrasted with others which had not undergone the process, and were in all cases decidedly superior."

Agents:—Messrs. G. Gibbs, 26, Down-street, Piccadilly; Thos. Gibbs, corner of Half-moon-street, Piccadilly; and Edw. Purser, 40, New Bridge-street, London. W. E. Rendle, Plymouth Manure Company; J. Campbell, 5, Mersey-street, Liverpool; F. Bruce, Merchant, Hull; Crouch and Co., 66, Close, Newcastle-on-Tyne; W. F. Karkeek, Truro; John Mayer, High Offley, Staffordshire; George Griffith, Bewdley; J. B. Baden, Warminster; Phillips and Whittem, Coventry; John Towers, Maidenhead; Samuel Waldie, Carlisle; John Rodway, Carmarthen; James Black and Co., Aberdeen; W. Campbell, Merchant, Wick; Wm. Cuthbertson, Printer, Annan; J. and D. Campbell, Thurso; Maxwell Dick, Irvine; Dickson and Turnbull, Perth; Drysdale and Co., Glasgow; Drummond and Sons, Stirling; Wm. Dalrymple, Cupar Angus; John Dykes, Kilmarnock; James Haldane, Lauder; J. Bell, Dundee; Thos. Kennedy, Dumfries; A. Kennedy, Thornhill; P. Lawson and Son, Edinburgh; Wm. Low, Forfar; A. M'Farlane, Kinross; John Ogg, and Shield and Co., Arbroath; Geo. Robertson, jun., Kirkwall; John Rae, Elion; A. Simpson, Macduff; A. B. Telfer, Ayr; Wood and Co., Stonehaven.

The Agricultural Gazette.

SATURDAY, SEPTEMBER 14, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

FARMERS' CLUBS.

Sept. 20—Debenham, Stoke Ferry, Wrentham.
Sept. 21—Cardiff, Gloucester.
Sept. 23—West Hereford, W. Firle, Fairford, W. Market, Yoxford.
Sept. 26—Framlingham, Isle of Thanet, Rayleigh.
Sept. 20—Richmondshire.
Sept. 27—Halesworth.

THE month of August is the gala month of British Agriculture. To those who would estimate its resources, its capital, energy, and skill, no season is so favourable; for the success arising from their application is at this period evidenced both in the golden maturity of our crops, and in the splendid Exhibitions of stock and mechanical ingenuity which OUR THREE NATIONAL SOCIETIES afford us.

Not only do the Exhibitions of these Societies promote improvement in stock and machinery, but indirectly they cannot fail to diffuse agricultural knowledge and improvement in general. For can it be supposed that great numbers of persons, from all parts of the empire, can be brought together at a season when the success or failure of the previous year's operations are written on the face of the country, in a language so plain that he who runs may read, without much information being received? And we cannot suppose that, coming as they do with minds ready to criticise what they see and hear, men of science, practice, and capital, can associate without much that is useful being conceived and propounded. From these considerations, therefore, it is obvious that the results of our Annual Agricultural Meetings constitute a meter by which may be indicated to us the intensity of that energy in agricultural improvement which has already done so much for the country. One pleasing feature developed at these meetings promises us important results, viz., the desire which was everywhere apparent to seize the opportunity presented by the assemblage of scientific men, in order to unite scientific knowledge and practical skill in the investigation of subjects of agricultural interest. And the necessity for such an investigation exists all the more, because the results of discussions at Glasgow simply prove our entire ignorance of many of them. It is thus alone that we may expect improved methods of culture to be made known, the causes of failure in our crops to be ascertained, prejudices to be removed, knowledge to be diffused, and a spirit of observation and inquiry to be encouraged.

The actual results of the meetings alluded to are, however, the best illustrations of what may be expected. Thus, at the Glasgow meeting "the best means of making Science promote the Practice of Agriculture," and "the Causes of the Failure of the Potato-crop," were discussed; and at the Southampton meeting of the Agricultural Society of England, and at the Irish Society's Show at Dublin, the subjects of "Agricultural Education;" of "the Best Description of Stock for special purposes;" and of "the Cultivation of Flax," were respectively mooted. The first of these is a matter of general and permanent interest. We have already seen morasses, waste lands, and heaths, converted, by its aid, into golden corn-fields and profitable pastures. Heather has given place to the Oak, and the rabbit to the sheep.

The cause of the failure of the Potato-plant, again, on account of the money value of the crop, is a question of immediate importance. At the present time especially, when that failure has been so general throughout the country, and when, in addition, the Hay and the Red Clover crop have also failed, and when, as report says, the Turnips are failing, it is worthy of most anxious investigation.

In estimating the importance of a knowledge of the *specific* qualities of stock, we must look only to two products—beef or milk, mutton or wool;—and some of our purest breeds of stock, and certainly of our multitudinous crosses, must be inferior to others in both these respects. The breeding and grazing of such is therefore a loss which might be prevented. The cultivation of Flax also—the subject introduced at the Dublin meeting—is not uninteresting to us. It has been shown to be a crop worthy of a place in the rotation of a judicious farmer on good soils; and to the farmer of poor lands, as well as to all, its cultivation is of consequence, for it provides us with Linseed-cake, one of the best substitutes for our green crops in a season like the present, and a most excellent fattening food in any season.

At present, of course, we cannot give even an outline of the information brought to bear on the subjects alluded to. Each is worthy of extended consideration. Our object now is merely to call attention to these discussions, as they indicate the existence and activity of a spirit of improvement, and as they evidence a power which our Agricultural Societies possess of promoting the progress of the science, and the practice of the art; and should the spirit of research and observation which was excited be the only result of these proceedings, that power will not be ineffective. "Let us," said Mr. Alexander, at the Glasgow meeting, "go home, and put in force the various suggestions we have heard; a little labour will enable us to test many opinions, and a little time put us in possession of a great amount of knowledge" The sentiment was unanimously applauded and appropriated. With this spirit abroad, can we fail to learn that from which safely to deduce principles whereby our practice may be regulated?

Let us, however, suggest that if it be intended to adopt the discussion of any question on a future occasion, the subject should be publicly announced, and our local clubs recommended to take it into consideration. The experience of the whole country would thus be brought to bear upon it, and the matter would be thoroughly sifted. In carrying out this design, instead of mingling argument with conviviality, and trusting to one or two speakers for information on any subject they may select, as is the case at our English Society's meetings, we would advise the adoption of the method practised at the Highland Society's Show at Glasgow, which is, to have public breakfasts, at which questions may be discussed, and information given or received by any one who may think proper to attend; these interfere neither with the duties of the day nor the pleasures of the evening. Anniversary dinners are unfitted as times for the discussion of business questions; after-dinner hours are as essentially the hours of relaxation and amusement amongst Englishmen as those before that period are of business and reflection.

On the strength of this peculiarity our Continental neighbours term us a "dining race:" and thus it cannot be expected that a concourse of Englishmen, with spirits elevated, can settle themselves down, contrary to their wont, after a day of pleasing toil, to the calm discussion of difficult questions. From neglecting these considerations many discussions at agricultural dinners have failed; and the extraordinary *éclat* with which those of the Highland Society went off during the last meeting, are undoubtedly to be attributed to the arrangement we now recommend—an arrangement which, by *discussing business at business hours*, does not oppose itself to the customs of society, but, on the contrary, enlists them in its service.

This lesson will, we trust, not be lost; it is not the first which we have with advantage derived from the experience of the *parent* Society beyond the Tweed. —*H.*

SEVERAL complaints have lately been made by Correspondents of the ravages of that extremely injurious parasitic plant—THE CLOVER DODDER. Many such complaints were made at this season last year, and they elicited from the scientific and practical readers of the *Gardeners' Chronicle* much useful information, from which, according to our last week's promise, we now proceed to make a few extracts. In the Number for Sept. 9, DR. LINDLEY writes as follows:—

"As soon as the seed of the Dodder is ripe, it falls to the ground, and usually seems to lie dormant till the succeeding year. When the spring returns, the embryo sends one end down into the earth to form a root, and with the other it rises upwards, like a small white thread or worm. At this time it is not a parasite, but seems to derive its food from the soil, like ordinary plants. It cannot, however, do so long, but withers and perishes, unless it touches some living branch or stem. If it succeed in doing so, it immediately seizes the live stem by means of a sucker, which is protruded from the point of contact; and then, twining from left to right, and forming more suckers as it twines, it establishes itself on its victim, and ceases to have any further connexion with the soil. From that time forward it is a true parasite, feeding on the juices of the plant it has seized upon. After making a few turns round the branch, and securing itself firmly in its new position, it again lengthens, and catches hold of some other branch, when more suckers are protruded; and thus it goes on—branching, and twining, and sucking, and branching again—until it forms that appearance which Professor Henslow well describes as resembling 'fine, closely-tangled, wet catgut.' Now the Dodder has a new and independent seat of life wherever it has twined round a branch; and as it is incessantly twining and separating, and twining again, a single plant is speedily in the condition of a polype—so that if it be cut into a thousand pieces, each piece will immediately go on growing, as if nothing had happened to it. Tearing the Dodder to pieces, then, so far from extirpating it, only multiplies the mischief, instead of arresting it.

"This short statement will show that it is a formidable enemy that has been thus unfortunately introduced to our fields; and, as these things are not very nice in their food, it is not impossible that the Clover Dodder may next take a fancy to our Wheat-fields, unless we can speedily put an end to its presence. It is of little use to cut it in pieces,—it is of no use whatever to do so, if the fragments are left where they can catch hold of anything else.

"As it is only an annual, it would be killed if we could prevent its flowering; but that is difficult, because of its hiding itself among the lower branches of plants, where it cannot well be seen: and a few heads of flowers will soon renew it in a succeeding year. The right plan would be to dig up the Clover where the Dodder appears, so as to form a circle considerably beyond the patch apparently formed by it, and then to burn it in heaps; or, in cases where the entire field is infected by it, to sacrifice the whole crop, and burn it. This may appear a violent remedy, but it is the only one likely to be effectual; and even this will fail, if (which is not yet the case, but soon will be) the Dodder is allowed to form its seed: for, they will fall on the ground, lie hid in the crevices, and reappear with the next crop,—when all the labour will have to be done over again."

The following remarks on the rapidity of its growth are by PROFESSOR HENSLOW:—

"I find one of the patches, which I stated to be two yards in diameter three weeks ago, is now six yards in diameter, which gives us a ninefold increase in area. The mere raking which this patch had received appears to have promoted the spread of the Cuscuta, possibly by having retarded the development of the flowers, and by thus fitting the numerous fragments left upon the Clover for making independent and more vigorous shoots. Another patch is now a perfect mass of cream-white flowers, upon which a number of flies have stationed themselves, in seeming enjoyment of the succulency of the heads of flowers. As you have thrown out a suggestion that this Cuscuta may possibly become a future pest in our Corn-fields, unless it shall be timely checked, I directed my attention to the plants upon which it is now growing, and I observed it was attached to and evidently attacking the following species:—Geranium dissectum, Daucus carota, Carduus arvensis, Euphorbia exigua, Viola tricolor, Malva sylvestris, Linaria spuria, Senecio vulgaris, Medicago lupulina, Alopecurus arvensis, and another Grass, which seemed to be Agrostis vulgaris."

The seed of this plant appears to have been imported from Cabul along with the seed of Trefoil. The following is an extract from the communication of a correspondent, with remarks by DR. LINDLEY:—

"I have the pleasure of sending you a packet *in the state in which it was purchased at a bazaar* with that which produced the Cuscuta above mentioned. Close examination may possibly detect the seeds of the parasite mixed with those of the Trefoil."

We have carefully examined the seed alluded to in the foregoing letter, and we are able to state that the seed of Cuscuta trifolii was in it. Out of a small packet we have picked *thirteen* seeds, each with its snake-like embryo perfectly alive and fit for growth.

We are also enabled to state something more important; namely, that the Dodder-seed may be readily separated by sifting. Lucerne-seeds are about 2 lines long and 1¼ broad. Clover-seed is much the same; the Dodder-seed is spheroidal, and scarcely a line in diameter. It is of a pale-grey colour, in form like the quarter of an Orange, and looks more like fragments of grey clay than an organised body.

In a subsequent paper we are informed that Dodder seed may be separated from Clover-seed by the use of the sieves called No. 17.

From the information thus accumulated, it appears that the existence of this weed in our Clover-fields is matter of serious importance. Those who have the misfortune to be attacked by it ought to place the spots where it has made its appearance under the strictest quarantine. Let them act upon Dr. Lindley's

advice, dig the land round the isolated patches to hinder it spreading further, and then carefully pare and burn the patches themselves.

ON FLAX-SEED AS FOOD.

(Concluded from page 610.)

Flax-seed, it has been already observed, is applied to the feeding of the various animals on the farm at Horkesley Hall, in the manner above described—a steaming apparatus having been recently erected there, instead of a common boiler, formerly employed. The arrangement of the houses and sheds for using the Flax-seed compound does not materially differ from that adopted at all the improved farmeries for stall-feeding. It is merely necessary to provide simple and convenient troughs to contain the food, which admit of being washed out with facility, to keep them sweet; and further, to provide a dry and comfortable bed for the animals. When fed on this compound, the quantity of urine will not, however, be so great as when Turnips are used; but the manure made when feeding on it is superior to that produced from any other kind of food. According to Mr. Blair Warren's arrangements, the liquid manure is not separated from the more solid matters, and hence no tank or reservoir is necessary for its reception. The sheds and other apartments in which animals are fed in this manner are slightly excavated, and in these the manure accumulates for weeks, fresh additions of litter being made as they are required. The troughs in which the food and water are supplied are of course fixtures, but arrangements are made for raising or depressing them, by means of a sliding groove, so that as the manure accumulates the troughs can be raised to the height most convenient for feeding from, and after the boxes are cleared out, the troughs are again lowered with facility. The treading of the animals prevents any considerable degree of fermentation from taking place until the manure is removed to the heap, and small quantities of finely-powdered gypsum are sprinkled over the surface, to prevent the escape of any ammoniacal gas which may be disengaged. This may appear to many a slovenly system of management, and one calculated to maintain the animals in a foul atmosphere; but such is certainly not the case. The manure thus produced, taking both the nutritious quality of the food and the plan of storing it into account, is the most valuable which can be conceived. The attention which is paid to properly littering the animals, and to prevent the formation of gaseous exhalations, effectually guards against the presence of any unpleasant smell. These circumstances it is particularly necessary to allude to, as Mr. Blair Warren conceives the increase in quantity, and improvement in the quality of the manure, which is effected by means of the system he follows, as important features in estimating its value; which they confessedly are. The smallest particle of liquid matters is not allowed to flow from the yards, and still the state of the manure at its removal does not indicate the slightest appearance of any excess in this respect. The animals have a perfectly dry bed; and cattle-sheds more free from any noxious effluvia than those now described cannot be conceived. At the period of the removal of the manure from the sheds, powdered gypsum is liberally employed in being sprinkled over it as it is freshly turned up, and by these means it is applied to the soil without being deprived of any of its fertilising properties.

There is, perhaps, no animal of the farm to which confinement in houses or sheds has been considered more unsuitable than the sheep, whether the inaptitude to take on flesh under such treatment, or the supposed tendency to become diseased is considered; but the success which has attended Mr. Blair Warren's management in this respect shows that such opinion is not well founded. A portion of his sheep get an allowance of compound, formed as already directed, on their pastures, and others are supplied with their food in the houses, in which they are divided into lots of half-a dozen each, when they put on flesh rapidly, being littered with Bean or other straw, which they convert into excellent manure. No arrangements are necessary in their case for carrying off any portion of their urine, which is absorbed by the litter, and adds to its value as manure. They are supplied with this compound four times a day, about a ½lb. of linseed and 2½lbs. of inferior grain being given to each animal in the twenty-four hours. During the summer months sheep may be advantageously fattened, penned on their pastures; but when the weather becomes cold they should be removed to the houses, to protect them from the vicissitudes of the weather, the injurious effects of which, as retarding the acquirement of flesh, I have already noticed in recent papers on the subject in the *Agricultural Gazette*. Even during the months of summer it has been ascertained that sheep may be successfully fattened in close houses, being there habituated to a greater uniformity of temperature than when in the fields—protected alike from the oppressive heat of the noon-day sun, and from the colds of the night.

The compound now under notice forms an equally valuable food for horses as for cattle and sheep, and is more highly relished by them than any other food which can be given them. Advantage may be taken of the nutritious properties of the Flax-seed, to substitute the inferior for the more valuable grain for horses, and this, too, without any loss of condition being occasioned. The sleek coat of such as are fed in this manner is quite conclusive as to the adaptation of the food to the animals. To feed farm horses economically their Hay should be cut into chaff, and mixed up with farinaceous matters, and the addition of the Flax-seed jelly enables this system to be carried into operation with facility. The quantity of Hay which a horse will destroy and consume when given to him in its natural state, is, in fact, more than double that actually required when cut into chaff.

But enough has, I trust, been said relative to the advantages of this system of feeding, to convince the most sceptical of its value. It, indeed, only requires a fair trial to insure its adoption. The following are a few of the returns which have been obtained by it at Horkesley Hall, selected almost at random from the farm accounts kept by the steward, which were kindly placed at my service. The quantities supplied to each of the animals have not been correctly ascertained, but a usual proportion has been about three parts inferior grain, and one part of Flax-seed meal, somewhat less than a stone of this mixture being daily consumed, with cut Hay and straw, by an ordinary sized bullock. As the details of Mr. Warren's system were not intended to be placed before the public, no comparative experiments as to the value of this compound and other articles of food have been made; but from the experience he has already had, he is quite convinced of the superiority of the compound to any other article of food, both as regards cheapness and the possession of nutritious qualities. The value of the compound is about 5*d.* per stone of 14 lbs.

A lot of heifers, 3 years old, which cost 10*l.* each, after having had a rather small allowance of Mangold Wurzel for a month, were placed on the compound on 21st November last, and sold on the 23rd January following at 9*s.* 2*d.* per score, dead weight, and realised at this rate, 17*l.* 16*s.* 1½*d.* each. This result would have been more satisfactory had the improvements effected by the first month's feeding on the Mangold Wurzel been ascertained.

A lot of two-year old bullocks were laid in on the 21st November, at 7*l.* each, and fed on compound with cut Hay and a small quantity of Mangold Wurzel daily, during a part of the time. These were sold in the beginning of May following at 14*l.* 10*s.* each.

Four two-year old steers, purchased on 29th December, at 6*l.* each, and fed in the same manner as the bullocks, realised 13*l.* each for six months' feeding.

A lot of sheep were laid in the end of September last, at 16*s.* 6*d.* each, and sold on the 13th July at 34*s.* 6*d.* During the last ten weeks these sheep were fed in boxes in the farm-yard on the compound, until which they had been folded on Turnips during the winter in the Turnip-field, and on Clover during the month of October.

Another lot of sheep were purchased on 17th June, at 22*s.* each, and sold on the 26th of August (last week), in Smithfield, at 29*s.* a head. These were folded on Clover by means of hurdles, and supplied with compound morning and evening in troughs in the field.

Further cases of the results of feeding on Flax-seed compound might be adduced, but it is hoped the foregoing will be sufficient to induce many farmers to give it a trial, and report also the results which they obtain. No additional apparatus will be required for the purpose, as it is conceived a Hay and Straw cutter, and machinery for bruising grain are already on every well-managed farm. A common boiler will, in the first instance, suffice for the preparation of the jelly, so that no extra expenditure need be incurred for fixtures until the result of any necessary experiments are ascertained.—*J. Sproule.*

MANURE FOR HOP GARDENS.

About this time last year I read an account, I think in the *Gardeners' Chronicle*, of a Vine-grower in Germany, who had manured his vineyard for some years with the cutting of his Vines. It then occurred to me that our Hop bines, now completely wasted—for they are generally burnt in the field to get rid of them—might be turned to the same use. Not being a Hop-grower, I got one of my tenants to cut up some of the bines into pieces of about one inch long. This was done with a common chaff-cutter at an expense of about 3*s.* an acre, *i. e.* cutting up the bines of one acre; part of these were spread dry into the ground immediately; the rest were put in heaps, of about four bushels in a heap, and covered with earth and left in that state to rot till the time for digging the garden, when it was found that the bine had decomposed into a rich black mould; this was spread about the land and dug in; part of this and part of those that were dug in in the autumn, were dunged with half the quantity of dung given to the other part of the garden—the other half had no dung. The bines throughout have grown as rapidly, looked as well, and at this moment the Hops appear quite as good on the part only manured with the bines, as where dung only was used; nor do I perceive any difference where the dung was added to the cut bines. My tenant is so satisfied with the experiment that he is now making a cutting-box to cut all the bines of his garden, as he is convinced that he will be able to save at least one half the expense of the dung, which he cannot put on under 5*l.* per acre. Now it appears to me but reasonable that this should answer, as it is returning to the soil in a state easily taken up by the growing plant, the very elements that had been taken from it the year before; and all that seems requisite to add is manure to make up for the weight of the Hop, which is carried away. As the cultivation of the Hop plant is very local, it is possible that this experiment may not have attraction for your general readers; still I am anxious to draw attention to it at this moment, when Hop-picking is about to commence, and earnestly hope that other Hop-growers will test the experiment apparently so successfully made by my tenant. —*John Maxwell Tylden, Milsted, Kent.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

(Continued from page 612.)

When the grain first cut becomes thoroughly dried and ready for removal to the stackyard, such of the farm-servants as are usually employed in driving horses are withdrawn from the reaping, for the purpose of leading in or conveying the Corn from the fields to the stackyard. The reaping, leading in, and stacking, are thus for some time carried on simultaneously. The corn-carts previously noticed, of which every farmer has a few, are now put in requisition; but when a sufficient number of these are not obtainable, frame-works fastened to close carts are made to answer the same purpose. A man attends in the field to fork the sheaves to each set of carts, leading to one stacker, and a boy or woman is employed in raking up any stalks remaining on the ground after the stooks are removed. Another boy is also occasionally required on the stacks to hand the sheaves to the builder.

The stacks, which are always circular in form, vary in size according to the kind and condition of the crop and the taste of the farmers. Some take a pride in erecting and possessing gigantic Corn-stacks, notwithstanding the manifest loss of valuable time which their building necessarily occasions. When the Corn has been well won, and got in in a dry state, the stacks are made of large dimensions, but if imperfectly dried, smaller sized ones are adopted. The usual breadth at bottom for Wheat-stacks is 16 feet, and for Oats and Barley 14 feet. It is held as a general rule by East Lothian farmers that all Corn-stacks should be made only of such a size that one of them may afford employment to the threshing-machine and the persons attending it for a yoking of five horses, two such stacks being threshed and dressed in a day. Stacks of this size will contain from 25 to 30 qrs. each, according to the quality of the Corn.

Corn-stacks are now generally built upon raised stands supported by low cast-metal pillars, having projecting caps at their upper extremity, on which the frame-work of the stand rests. The caps also prevent the entrance of vermin into the stack. These stands are usually of a septagonal form, and when firmly constructed, with the timber frame-work of substantial materials, will last for a very long period. They not only admit of stacking the Corn much sooner than what can be done with ground stands, but also effectually prevent the depredations of vermin. Cast-metal stands of this description may be put up in the most substantial manner for about 2*l.* 10*s.* each—a sum which they will soon amply repay. Elevated stands of a more temporary and less expensive character are employed by some farmers; instead of the cast-metal pillars, ones formed of wood or stone are used, upon which the most suitable sticks which can be conveniently procured are placed, without any further preparation; but these require to be renewed or repaired every year. These stands are here commonly formed without the usual accompaniment of a conical funnel projecting perpendicularly from the centre of the frame-work.

Although raised Corn-stands of either of the above descriptions are now pretty general throughout the county, stacks are still not unfrequently formed on the ground, in which case the site on which to build the stack is usually prepared in the following manner:—The centre of the site for the intended stack being ascertained, a stout pin of wood is there driven into the ground; three sticks previously prepared, of an equal and suitable length, and connected at the top by means of a pin passing through perforations in them, are then planted in an upright position over the centre, and the lower extremities of the sticks are stretched out in a circular manner around, and about 3ft. from the centre. A straw rope is next wound round the sticks near the ground, for the purpose of preventing the sheaves from falling into the open space. A tress* from 3ft. to 4ft. in length, made for the purpose, and fixed on the site between the funnel and the margin, allows the free access of air into the interior of the stack. A layer of dry straw placed on the ground, and made circular by means of a string attached to the pin previously inserted to mark the centre, completes the preparation of the site. When the Corn is considered to be sufficiently dry, the funnel or kiln, as it is also termed, is omitted as being unnecessary.

The manner of forming the stacks themselves need not be here described. The head, or conical part, is made rather smaller now than formerly, in order to economise time and straw in thatching. As the kiln or open space in the centre of the stack seldom reaches to the eaves, it is customary to continue the aperture to near the summit by means of a sack filled with straw, which is pulled up as the building proceeds. A flat board is then usually laid across the stack, on which a few draining-tiles are placed. There is thus formed the means of an uninterrupted circulation of air throughout the interior of the stack, from its base to its summit, the influence of which upon the quality of the straw and grain is obviously beneficial. After being built the stacks are thatched without delay, if the weather appear unsettled, but in most cases they are allowed to subside for a few days. Three persons are engaged together at the operation of thatching—two on the stack, one above another, and one on the ground, to fork up the bunches of drawn straw used as thatch. When thatched, the stacks are immediately roped, to keep on the straw. One of the thatchers remains on the stack for this purpose, standing on a long ladder, while the other descends to assist the men already on the ground in fastening the extremities of the ropes either to the stack itself, or

* Similar to those used by builders for supporting platforms, &c.

what is most general, to a stout rope passing round it immediately below the eaves.

In consequence of the variable climate to which this country is subject, much damage is often sustained by the Corn, from sudden or unexpected falls of rain. To be, in some measure, prepared for such contingencies, it is customary on some large farms to have a band of men solely for carrying on the process of thatching and roping. The usual practice is only to half rope the stacks at first, and afterwards to return and finish them off in as neat a manner as time will allow.

Harvest-time is peculiarly a period of anxiety and exertion. No useful hands are then allowed to remain inactive, and no time is permitted to be lost or trifled away. Economy of time and labour is shown in various ways. The straw ropes employed in securing the thatch upon the stacks are manufactured on the wet days occurring during the summer and harvest. Straw is also drawn into bundles for thatching when other operations cannot be carried on. In the wet and dewy mornings, when the leading in is suspended, the men engaged at it are busily employed in setting up fallen stooks in the field, in thatching and roping stacks already erected, and in preparing sites and kilns for others. By a studious attention to these minutiæ of management, the men are seldom employed at any operation on a dry day that may be done in a wet one; the main work is never delayed when suitable weather for its performance occurs, and much valuable time of men and horses is consequently gained.

Many of the stack-yards deserve a passing notice, not only on account of the plentiful appearance they present after the in-gathering of the harvest, but also from the manner in which the ground is arranged. If naturally wet it is in most instances perfectly drained, and afterwards disposed into wide ridges raised in the crown, and every third one reserved for a road, which is covered with broken stones, coal-cinders, &c. A low stone dyke frequently incloses the whole. An elevated well-exposed stack-yard is, for obvious reasons, always preferred. Wheat and Beans, particularly the latter crop, which, from the succulency of its straw, and the late period at which it is cut, is peculiarly difficult to be got sufficiently dry in unfavourable seasons, are often stacked by themselves in some exposed situation near the field in which they grew—a practice by which the best samples of grain are obtained.—*T. Sullivan.*

ON MINERAL AND INORGANIC MANURES.
No. XXV.

By Professor Charles Sprengel.

(*Continued from page 570.*)

b. Ashes of Soap-boilers.—Formerly all ashes of soap-boilers consisted of extracted wood-ashes and lime, the latter either caustic or combined with carbonic acid. They were, therefore, a superior manure, as they improved vegetation by the phosphate of lime, magnesia, and gypsum, as well as the lime admixed. Since, however, many soap-boilers used soda instead of wood-ashes or common salt, ashes are turned out which consist merely of caustic lime or its carbonate, which have, therefore, not so much value as mere burnt lime. Whoever, therefore, purchases ashes from soap-boilers has to attend to that.

If the ashes of soap-boilers consist of extracted wood-ashes and lime, they are amongst the best mineral manures, still a good marl is always preferable, as any one can see by comparing the chemical constituents of both.

How they act on the ingredients of the soil, does not require to be again referred to in detail. It is also superfluous to speak on the manner in which they nourish plants, as everything just said of extracted ashes applies equally to these. It is the general opinion, that the ashes of soap-boilers act especially by the potash contained in them; but this is a mistake, because, although I have several times subjected them to chemical analysis, I have always found but small quantities of that substance. 100,000 parts of a sort of soap-boiler's ashes, which experience had proved to be a superior manure, consisted of

35,000	parts	of silica.
35,010	,,	lime, mostly in a caustic state.
2,330	,,	manganese.
1,500	,,	alumina.
1,700	,,	oxide of iron.
1,840	,,	oxide of manganese.
0,500	,,	potash, combined with silica into a silicate.
0,180	,,	soda, ditto.
0,190	,,	sulphuric acid, combined with lime into gypsum.
3,500	,,	phosphoric acid combined with lime.
0,090	,,	common salt.
18,160	,,	carbonic acid, combined with lime and magnesia.
100,000	parts.	

Of soap-boiler's ashes, 2000 to 3000 lbs. (in a dry state) are generally used on one acre of land. By 3000 lbs. the soil would obtain about 920 lbs. lime, 70 lbs. magnesia, 15 lbs. potash, 5 lbs. soda, 12 lbs. gypsum, 230 lbs. phosphate of lime, and 8 lbs. common salt, by which it is to be seen, that they owe their manuring properties mostly to caustic and the carbonate of lime, to magnesia and phosphate of lime; as their 15 lbs. potash, 12 lbs. gypsum, &c., may produce a very inconsiderable effect, the more so, as the potash is also combined with the silica into a substance not soluble in water.

After manuring with soap-boiler's ashes, plants of the Clover tribe will grow best, but all other crops will be benefited; and the fresher they are, the more effective, as they then contain much of caustic lime, by which, especially, the carbonic humus, or the organic matter in the soil are affected, and changed into humic acid. Soils which contain very little lime, will be always best improved by them, and in this case they will be very useful, whether employed on fields or meadows. According to the amount used, this effect will last six to nine years; which, however, will be only the case when the soil is not deficient in humus, and such other substances of which the ashes contain but a small quantity.

Soap-boiler's ashes are strewn (like wood-ashes) either over the crops already growing, for instance Clovers, Lucerne, Grasses, &c., or they are harrowed in with the seed of the winter or summer crops, and they act partly like extracted ashes, and partly like caustic lime; they can be also used to great advantage on new marshes.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(*Continued from page 579*).

Lower Lias.—With the exception of the Bath stone—the uppermost member of that portion of the oolitic series which we have described—the strata constituting the lower, or as it is generally termed, the Blue Lias, cover a greater portion of our district than any other occurring within its limits. From the edge of the hills, under which it dips, being overlaid by the rocks we have already described, it extends to the Severn, at Purton Passage and beyond the northern limits of the district. From Purton Passage, where it overlies one of the members of the Silurian series, its western boundary runs south-east, near Berkeley. The marl of the new red sandstone here appears below it, and the junction of the two is easily traceable by Lower Wick Green, along the edge of a slightly rising ground by Charfield, up the eastern side of the valley which extends beyond Wickwar. Here its boundary is irregular; the rock being intersected by valleys exposing the marl and magnesian limestone of the new red sandstone. From Wickwar, the western limit of the lias runs south by Sodbury, overlying the old red sandstone and the mountain limestone, along the edge of the basin already described, of which, with the marl of the new red sandstone there exposed, it forms the eastern boundary. It passes Waterleigh, Siston, and Doynton, leaving exposed there a small district very curious in a geological point of view, which shall be described in its proper place. From Doynton it runs south-west by Barrow Hill, &c., to Hanham, where the line of its junction with the new red marl crosses the Avon to Keynsham, and thence it lies along the irregular edge of the hills to Bristol. Besides this tract, which extends the whole length of our district, and varies from upwards of four miles as at Purton and Pucklechurch to less than one mile in width, as at Wotton-under-edge, there are numerous cases in which it occurs in smaller extent capping the hills and covering the highlands which occur on the other side of the basin. Thus, proceeding from Bristol to Gloucester, the first ten miles of the road lie along a district of this kind. The boundary of this tract, commencing at Montpelier by Bristol, runs along the edge of the hills by Stoke as far as Itchington, where it crosses to Abbey Common by the Gloucester road, overlying the mountain limestone between the two places. From Abbey Common it proceeds by Alveston, Almondsbury, Over, Compton, round by the edge of the vale of Henbury, by Charlton, above Westbury, near Redland, to Montpelier, whence we started; thus inclosing a tract of about 20 square miles in extent. Besides this, which is by far the most extensive of these outlying masses of lias, it occurs at Aust, at Henley Hill, and the hills overlooking the town of Thornbury, on the south; at Eastwood hills, and Whitecliffe Park, near Berkeley, overlying the new red marl. It also covers the red marl at Tortworth-coppice, also between Charfield and Wickwar. Its occurrence so frequently, and at such distances on nearly one level, shows that at one time it must have covered nearly the whole of the vale. The lower lias consists of two members:—an impure limestone-rock, of a blue or white colour, deposited in layers varying from 6 to 10 inches in thickness, with thin seams of clay between them; and a stiff calcareous clay, of a blue or yellow colour. This last is the general character of the lias in the northern part of the vale. There is little or no rock to be found north of Almondsbury, Stoke Gifford, and Westerleigh. To the south, however, of a line drawn through these towns, the lias consists chiefly of the rocky member. The lias varies in thickness; in one instance, at Codrington, it thins away altogether, and leaves a tract of mountain-limestone exposed in the midst of it. The rock of the lias is burnt for lime when lime of a better quality, as at Stoke Gifford, Bristol, &c., cannot be had in sufficient quantity. It is suited for underground and water-works; the price is generally 18*s.* a hundred bushels. The chief portion of the expense in the quarrying consists in the necessity of removing the great quantity of clay between the beds of rock; and hence, a quarry is frequently carried over the whole extent of a field, three or four only of the beds being dug, and the surface being thus lowered 2 or 3 feet as the quarry proceeds. In the northern part of the vale—at Slimbridge and Frampton, &c.—the clay of the lias is covered by beds of gravel, as has been already said.

Agricultural Character of the Lias.—The surface of this formation is in the northern part of the district, which is chiefly clay, nearly level, the undulations being very slight. South of Westerleigh and Dyrham, however, where it is chiefly rocky, many valleys intersect it, leaving ridge-like hills and abrupt eminences. It is very much covered by wood. This wood is chiefly Oak. Down at Purton Passage the country has a most forest-like appearance, and this is generally the case over the clay of the lias. Thus, at Hawksbury, several square miles of an Oak plantation occur on land otherwise worth very little, as is attested by the wretched state of the commons surrounding it. On the rocky part of the lias the country is not so thickly wooded; a view of the country in the neighbourhood of Pucklechurch from Hinton Hill, near that town, is very bleak. The soil on the lias is of two kinds. It is clayey or brashy, according as it is on the clay or the limestone. North of Almondsbury and Dyrham it is a dark, nearly black calcareous clay, the subsoil being either blue or black. In the neighbourhood of Newport it is a brown or light-coloured clay, the subsoil in this case being of a yellow colour. Towards Doynton and Wick, the soil is a black clay, full of fragments of the blue and white limestone, on which it rests. Over the whole of the formation the land is almost entirely in pasture, which is very much overshadowed and soured by the hedgerow timber. The fields are generally small, and the hedgerows wide. The pasturage is of a very poor kind, as might be expected on a soil which is so thoroughly soaked during six or eight months of the year. It consists, in great part, of Sedges, with a few plants of Plantain, and plenty of Rushes. The way in which these dairy farms are managed varies greatly. It is generally allowed that, to take more than one, or, at the most two, successive crops of Hay off the land is bad management. The value of the spring feed is nothing; the land being rarely in a state fit to allow of being stocked, till it is time to shut it up altogether for the Hay crop. The Hay is harvested in the month of July. It seldom averages more than 15 cwt. per acre. After mowing, the land is stocked till November, or later, if the land be sufficiently dry. If a crop of Hay is to be taken next year, the farmer tries to manure so much of his land each year. This is sometimes laid on not long after the mowing, in August or September, though generally it is done during the frosts of winter. If the land is not to be mowed the next year, this manuring is put off till next autumn, the land being depastured during the interval. In general, however, one year's grazing supplies the place of manuring. After all, the manuring the land receives is not calculated to do it much good. The scrapings of the ditches, mingled with the droppings from the cows that have been collected from the fields, where they have been consuming the Hay during the winter and spring, is all that it gets, and this is not laid on plentifully. In a great many instances, however, the land does not receive such good management as this. Frequently two-thirds of the land is mowed, and the other third depastured each year; that which is furthest from the buildings being mowed, and that next the farm and the buildings, and therefore more convenient for the dairy, being grazed. None of this land is efficiently drained; it is always soaked during winter; indeed, the farmers deny that it is possible to keep it dry. The prejudice, however, which still exists in many places against underground draining, is disappearing gradually. Many farmers would willingly pay 5*l.* per cent. on money laid out by the landlord in this way. But the chief way in which water is carried off is still by open gripe, which are cleaned out once every two or three years, and the earth laid in heaps and mixed with the cow-droppings to be spread over the land. The mole-plough is in considerable use also. It is either worked by a windlass or by horses—in the latter case a great many are employed; I know of one instance in which eighteen horses in a row were used by a farmer to make a drain only 18 inches deep. The loss of power in such a case must be immense. A more effectual way of draining land is also to a considerable extent adopted; this is termed clay-draining. The labourer stands on the surface of the ground, and, with a tool for the purpose, digs a trench about 20 inches deep, 2 wide at bottom, and perhaps 10 at the top; after clearing this out, he uses a wooden mandril, made of pieces of wood of the size of the drain, connected together by hinges, so that it is to a certain extent flexible; this fits the bottom of the trench, and fills it up to a depth of 6 or 7 inches; clay is hammered on this, and the drain is filled in; the mandril is then drawn forwards, clay is hammered down on it again, and the drain is again filled in, and so the work proceeds. This is much more effectual than the mole-plough, but not so permanent as draining with stones or tiles. The general objection to draining deep with tile or stone is the statement that water will not sink through the clay to them; the use of the subsoil-plough is thus called for, and if the pastures were broken up and well cultivated, and properly laid down again after the use of this implement across a thorough drainage with tile, their value would certainly be greatly increased. This effect would also probably follow the use of the mole-plough across the direction of deep stone or tile drains, although the land were not ploughed up, but merely pastured with sheep for four or five years. There is, as has been said, very little arable land on this soil. Many farms are entirely pasture; some, however, have a few acres under the plough. This is generally cultivated without any system, Wheat and Potatoes being the chief crops, and these are taken to supply the house. When it occurs in larger quantity the system on which it is cultivated is not only generally faulty, but the way in which it is carried into effect is slovenly: in many instances nothing but Tenales are grown, of which occasionally good crops are raised on this soil; but these will not pay for the injury which the land must receive from so scourging a crop, repeated so many successive years.

There are many instances in which a farmer, who has obtained permission to break up a field of Grass, has taken crops of Wheat after Wheat off it, until the land would not carry it any more, and then having laid it down for a series of years, till it is refreshed sufficiently, has broken it up again to give it the same treatment. The general rotation on the lias is a three-year course—Wheat, Beans, fallow. The kind of Wheat sown is the Blue Cone or Red-straw Lammas; generally the former, which seems to be well suited for a stiff clay. Eighteen or twenty bushels per acre is an average produce. This is a very low one for a clayey soil, but it is owing to the extreme state of wetness in which the land lies during six months of the year. If the land should get worn out with this treatment, it is laid down for several years; a very small crop of seeds is, however, obtained. Occasionally a portion of the land in fallow is sown to Vetches, which are cut for the stock. In some districts a crop of Oats is taken between the Beans, and the fallow, or Vetches. The crops then come round once in four years; viz., 1st, Wheat; 2d, Beans; 3d, Oats; 4th, Vetches, or fallow. This formation, when compared with the others in an uncultivated state, is certainly one of the lowest in the scale of fertility. This is well seen in Wickwar and Yate Commons. The land is covered with brambles and briers, the scanty pasturage being nothing but Sedges and Rushes. The Sloe and the Thorn, indeed, are not confined to the commons; it is hard to keep them out of the pasture lands. This aptitude to grow Thorns may almost be made a means of laying down the boundaries of the formation. Thus, on going from Alveston to Itchington, the Thorns disappear entirely as soon as we step off the clay of the lias on to the rock of the mountain limestone. The lias joins on to the gravel and the marlstone, by which it is covered, and to the new red sandstone, the mountain limestone, and old red sandstone, which it covers. In none of these cases but that of the gravel, which has been already mentioned, is that increased fertility consequent on a mixture of the two rocks observable. At its junction with the mountain limestone, the soil on the lias is benefited, or otherwise, according as the clay thins off abruptly or gradually from the rock. In the latter case the nearness of the rock to the surface acts as a drain. The improvement, which in some instances, I was told, existed in the nature of the soil just at the junction of these two rocks, is due more, I think, to this drainage than to any mixture of the clay and the limestone. The lias is the first formation we have mentioned, on which, within this district, the use of lime is sanctioned by experience. On most of the arable land on this formation, lime is used to the extent of about 70 or 80 bushels per acre. It is laid generally along the headland of the field on which it is to be spread, and being covered with earth is allowed to slack perfectly, after which it is carted or wheeled over the ground. The expense of liming, and all the chief expenses of cultivation, are made to precede the Wheat-crop, on which principally the farmer depends for his return. I met on this soil, near Frampton, with a curious instance of the extent to which long experience and observation may teach the same lessons as a knowledge of the science of geology would lead to. It was observed by a farmer, over whose farm I had been walking, that a good soil never existed where those shells (pointing to a number of fossil shells in the soil) were found in it. The shell was a graphite characteristic of the lias. The experience of the agriculturist had led him to connect the faults of the soil in some way with the existence in it of these shells. The geologist would at once know the nature of the subsoil from their presence in such abundance; and, throughout this district at any rate, the soil over that subsoil is bad.

Home Correspondence.

Woes of Farming.—I am a little man, with a little land, no experience, very little money, and a very great demand for it. I wanted to make my capital of 1000*l.* work a farm so as to keep myself and family in comfort, my daughters playing their piano, my horse having his groom, and I some good old port in the cellar for myself and friends. This was, I think, a very natural desire; and an old friend of my father's who had been a farmer in 1810, and had made a fortune, told me that I might be sure to do well, if I was but attentive to my business. Well, sir, I took a farm of 100 acres two years ago, and I paid great attention to it for a twelvemonth; but at the end of the year I found my capital all gone, although I took all the care I could of my money. Seeing that affairs had taken such a bad turn, I borrowed another 1000*l.* of my brother-in-law, discharged my bailiff, and took to farming scientifically. I bought guano, nitrate of soda, Potter, Poittevin, and Humphrey; but one turned out clay and brickdust, another salt, while chalk, charcoal, and sawdust was all I could make out of the others. They seemed to be no good, but I was told they were scientific, believed, and tried them. And now I am worse off than ever; I have wasted my own money, I have spent my brother's, and what is worse, I am deeply in debt. What am I to do? It seems to me that the friend who recommended me to take to so beggarly a trade as farming ought to pay my losses. But he will not; in fact, he says I am a lunatic, and fit for nothing but a strait waistcoat. I answer, I have straits enough without that, and I hope you will advise me what I should turn to next.—*Edward Pinthorn, Barkinfield.*

[It seems to us that the friend is right, and that advice is wasted upon one whose ignorance is even greater than his folly.]

Allotments.—A stranger hearing that I let land near the Seahouses, Eastbourne, at 1*l.* a rod, which is 8*l.* an acre, including rates, tithes, and taxes, blamed me, supposing the rent unreasonably high. When Benjamin King, who receives the rent of upwards of 400 allotments for me, was called in, he said not one farthing rent had been deficient in ten years, and that he had more applications for allotments at 8*l.* an acre near the fishermen's houses, than at 4*l.* near the church, though before the little tenants broke up the old turf it was called poor, sour land; and B. King said this land at 160*s.* an acre was more coveted than land at 6*s.* an acre on Beachy Head, also including rates, tithes, and taxes, though this last land had at that rent yielded the tenant at the rate of forty-eight bushels per acre of Wheat—I think the 7th year after breaking up the turf, which as a sheep-walk does not keep one ewe per acre. The land on the Down was not equally coveted, because it was two miles off, and up an ascent of 500 feet, which could not be accomplished at the odd hours which the land near at hand profitably employed. I presented, as dessert, to the stranger who objected to 160*s.* per acre, rent, rates, tithes, and taxes, a Cabbage—one the tenants had just given me—which weighed 22 lbs., produced by means of the manure his fish afforded. If gentlemen would oblige their neighbours by accepting the high rents their neighbours would gladly tender them, all parties would be served. Near Penzance, in Cornwall, about 20 years ago, 1000 acres of land were let for 10,000*l.* a-year; and Mr. Cuthbert Johnson's pamphlet on liquid manure, sold by Ridgway, says, the Grass lands round Edinburgh, watered by the town drainage, are yearly let in small portions by auction, at from 20*l.* to 30*l.* per acre; 130 acres belong to W. Miller, Esq., and the rest to the Earls of Moray and Haddington.—*M. A. G.*

Wide Drilling.—In the *Gazette* of 6th July, "Home Correspondence," this subject is treated of by "Lusor," referring to your article on the subject in p. 413. Having referred to it, I now send you an experiment of my own, made last year on Wheat. In farming my own land for the last eight years, I had always used a Suffolk drill for grain crops at 10 inches apart. Last year I had convinced myself that 12 inches would be better, and from 5 to 6 pecks of seed per acre instead of 3 bushels, usually applied; being of the same opinion on this head with Mr. Hewit Davies, who has written on this point. I was, however, induced to make a practical experiment on a wider drill, through my becoming acquainted with the results of a crop of Wheat—Golden Drop—which a neighbour had harvested the year before, put in at 2 feet apart in his swy brush land; he reaped a most abundant crop. Not having had all the results of his experiment, which I found had been carelessly carried out, until January last year, I had not time to try a similar one at my autumn sowing, so I determined to make a spring experiment of it, on a close of land that had been part of a coppice wood which I had grubbed up four years previously, but had not had Wheat in it before, and was then preparing for Beans, being heavy rich land, shallow, brush sub-soil. I, however, marked out two plots of 10 perches each, adjoining each other, and had the seed hoed in drills, north and south, one at 1 foot, and the other at 2 feet, as follows. It came up well, and progressed admirably. There were no weeds;—it was hoed at the commencement twice.

No. I.—Seed, Red-straw Lammas—the Wheat which suits this neighbourhood best. Hoed in on the 18th Feb., 1843, at the rate of 5 pecks per acre, in drills 1 foot apart, in a direction north and south, on 10 perches of rich heavy land; harvested September following, threshed, cleaned, winnowed, and weighed immediately:—

Produce of grain	2 bushels
Weight	124 lbs.
Straw	270 lbs.

Good sample and very little tailing.

No. II.—Seed, same as No. I. Hoed in same day, but with little more than half the quantity of seed, viz., at the rate of 3 pecks per acre, at 2 feet apart, on 10 perches of same land, and adjoining No. I.; harvested the same day:—

Produce of grain	1 bushel 3½ pecks
Weight	114 lbs.
Straw	284 lbs.

Sample better than No. I.

The Red-straw Lammas is essentially a winter Wheat; the crop, therefore, would have been greater had it been put in in November instead of February; or, if I had used a spring Wheat instead; and it being close to the wood the birds attacked it greatly. I have not thought it worth while to make another experiment as to 2 feet-drilling, because I am convinced that such a distance could never answer as a universal method, it being too far apart to support itself in exposed situations. The above results of No. II. would have been greater had it not been partly laid: the sheltered situation saved it from being more so. This experiment has, however, been a useful one. It clearly demonstrates that Wheat requires space to expand its roots in; therefore, broad-cast or narrow drilling cannot be a correct method. My crops of Wheat this year, just harvested, being very fine and abundant, all drilled in at 1 foot, with 5 pecks of seed only, there will be very little tailing. As the above experiment may be worthy of your notice when making a comparison with the others, I understand from the *Gazette* to be in progress, I have thought it well to send it you.—*Henry T. Davis, Waterhouse, near Bath.*

Wide Drilling and Dibbling.—Having recently observed in your Paper, and in others, several paragraphs on the advantages of dibbling seed-corn, and of sowing a much smaller quantity of seed than is usually done, it occurs to me that the result of a small experiment I made on a patch of ground adjoining my garden might not be uninteresting, and, by confirming previous statements, might lead others to make experiments on a somewhat larger scale. The following Tables will furnish you with the particulars of my experiment:—1st. As to produce of a single grain of three kinds of Wheat. 2dly. The total produce of 50 grains of the same description; and 3dly. The quantities per acre.

TABLE No. I.

Time of Sowing.	Sort of Wheat.	Quantity Sown.	No. of Ears Produced.	No. of Grains.
Nov. 18, 1843 ..	Red Lammas.	One Grain	20	1207
Ditto	Creeping Red.	Ditto	34	928
Ditto	Prolific.	Ditto	31	1040

TABLE No. II.

Time of Sowing.	Description of Wheat.	Quantity Sown.	No. of Grains destroyed.	No. that produced Corn.	No. of Ears produced.	Average No. of Ears to each Corn.	Total No. of Grains.	Measure of Grain.	When Cut.	Quantity of Ground.	Mode of Planting.
1843, Nov. 18	Red Lammas.	50 Grains.	16	34	642	19	19,128 or 562 to each grain.	2½ Half Pints.	Aug. 1st, 1844.	12 square feet.	Dibbled 6 in. apart
Ditto.	Smith's Creeping Red.	50	15	35	765	21	19,925 or 569 to each grain.	2¾ Half-pints.	Ditto.	Ditto.	Ditto.
Ditto.	Smith's Prolific Red.	50	12	38	637	16	19,711 or 518 to each grain.	2¾ Half-Pints.	Ditto.	Ditto.	Ditto.

TABLE No. III.—Produce per Acre.

Description of Wheat.	Quantity of Seed.	Quantity Produced.	Weight per Bush.	Quantity of Straw.
Red Lammas.	121,000 grains or six 4-5th quarts.	66 Bshls.	60 lbs.	65 cwt.
Smith's Creeping Red.	Ditto.	70½ Bshls.	62 lbs.	49 cwt.
Smith's Prolific Red.	Ditto.	66 Bshls.	60½ lbs.	63 cwt.

In order to form a correct judgment of the above Tables, it is necessary that I should add some particulars. There is no doubt the produce would have been very much greater, had the season and other circumstances been more favourable. The loss sustained in various ways is far more than any deduction that may properly be made from the above figures, as being the result of a garden experiment. In the first place, the soil, though recently broken up, was unfavourable for the season—a stiff, dark, heavy loam (lying in a clay subsoil), full of vegetable matter and very wet; the consequence was that about one-third of the whole plant was destroyed by the slug, and the rest was much weakened; again, the long-continued dry weather, although generally favourable for the Wheat crop, in this instance was otherwise, as nearly all the outside plants were injured by the roots being so much exposed, through the very large fissures in the soil. Although the average number of ears to each grain is about 19, in many cases only 6 or 8 ripened; the remainder died away, having become loosened from the ground. Very considerable additional loss was sustained by the birds; for although I had a girl five weeks tending it, yet of so little effect was it, that in order to secure it at all, I was obliged to cut it quite green, which very much lessened the bulk—of course, not only the measure, but also the weight. I have, however, given you the exact result. The samples and quantities answering to the above Tables I have by me, and may add that I have seen to the matter entirely myself. I intend this autumn planting an acre on the same principle. I hope others (practical men), will be induced to do so, as it is by experiment alone that the comparative merits of thin and thick sowing can be ascertained.—*E. W. M.*

Potato Failures.—I quite agree with Mr. Alexander's remarks in page 596, and think the following is a further proof of the correctness of the observations as to the land being moist, so as to bring out the latent powers of vegetation. A farmer near this for some years, and with great success, has adopted the following plan:—If the season be very dry he has the manure well watered before any of it is put into the drills; this causes a great moisture to the earth in the drills; no time is lost in getting the Potatoes in and closing them up. This year he has a most abundant crop, and his neighbours a complete failure whose manure was dry when put into the drills. Where guano and manure have been used together for Potatoes, they have answered well this season, and for this reason guano, when deposited in the earth, produces a moisture similar to salt when it dissolves in the earth, or by dampness.—*M. S.*

What is the action of common Salt on Carbonate of Lime?—I should be extremely obliged if any of your chemical readers would inform me whether salt and carbonate of lime (under the form of sea-shells) would, if

slightly moistened and left in great masses long together, act in any degree on each other? It is, I believe, known that masses of the same substances will act on each other, of which smaller quantities will not. I do not ask this question for agricultural purposes (though possibly the answer might be of some interest in that point of view), but from having found in Peru a great bed of upraised recent shells, mixed with salt, which are decayed and corroded in a singular manner, so that the surfaces of the shells are scaling off and falling into powder. I may mention, as explaining one element in the value of sea-shells as manure, that they are dissolved by water with greater facility than apparently any other form of carbonate of lime: one proof of this I observed in a curious rock, from Chili, chiefly composed of small fragments of recent shells, which are all enveloped and cemented together by a pellucid calcareous deposit; but in some parts of this rock the little included fragments are in every stage of decay and disappearance; in other parts they are entirely dissolved, the little calcareous envelopes being left quite empty. Here we see that water, capable of dissolving shelly matter, has penetrated through their thin films or envelopes of carbonate of lime, without having acted on them; these films, moreover, being a deposition from water within quite recent times.—*C. Darwin.*

Potter's Guano.—I received this analysis from Mr. Mason. The sulphate of soda cost me 3*l.* 10*s.* a ton, and was very good, with a slight excess of sulphuric acid, not injurious, I think, to vegetation. I obtained the sulphate of ammonia at 17*l.* a ton, but I diminished the proportion of gypsum and salt, in order to employ a larger quantity of sulphate of ammonia. A compound resembling the manure which you have sent me for analysis, may be made as follows:—

Bones ground fine	200 parts
Sulphate of lime	100 ,,
Common salt	100 ,,
Sulphate of soda	75 ,,
Sulphate of ammonia, mixed with urine.	25 ,,
	500 parts.

—*X.*

Guano; Superphosphate of Lime.—Last year I had some Guano sown over part of a field of Wheat, which had been manured with between thirty and forty bushels of lime per acre, in the autumn, at the time of sowing the seed. There was not more grain at the time of harvest, where the guano was sown, than where there was none, but much more straw. The expense of the guano appears to be almost thrown away. With regard to superphosphate of lime, I used about four bushels an acre, drilled with the seed; but from the strong and rank appearance of the leaves, I should think a less quantity sufficient.—*J. W.*

Transmutation of Species.—In Rodsley's "Annual Register" for 1759 (p. 381), is an account of some Oats which the second year produced in Sweden Rye, having been cut off two and three times. I sowed some in March, 1832, and cut them several times, but the roots died in the winter. The experiment was a source of great ridicule and amusement to my neighbours. Did not Bruce find Wheat apparently growing wild about the source of the Nile?—*C. M.*

New Soil.—Surely your correspondent, "Rambler," (p. 580), is incorrect in stating that Potatoes are generally better in a new than old soil. Every person I have conversed with on the subject, allows that the produce is larger [that is probably what he meant,] but that the quality is much inferior, being waxy. This year I had a piece of pasture double dug (the Grass sods being removed), and set with Potatoes and various manures; the quality from all the manures is bad.—*R. J.*

Clover Dodder.—I have inclosed a piece of what I believe is the Dodder plant, Cuscuta europæa, the stem being thread-like, yellowish, branched, and twining. The seed of this horrid parasitic plant I have no doubt has been introduced into our Clover in the foreign seed which is generally sold to the farmers. The havoc the Dodder has made amongst the Clover is quite astonishing; immense patches of yellow silk-like net-work may be seen all over one of the fields near this place, and in a field of my own, although I had taken the precaution to have a space cut all round the Dodder, and the plant itself cut and thrown together, yet so tenacious does it seem of vitality, that it has spread afresh and commenced blooming. I have this time had it cut and burnt, as I feared much that, should it be allowed to seed, I should have had a troublesome enemy in the land, awaiting to destroy any plant that might be brought or grown in its neighbourhood.—*Ruri rusticus.*

Failure of Hay Crop.—I do not see that your attention has been called to the serious consequences of the almost total failure of Hay in the grazing and dairy districts, where for the most part not more than 20 or 30 acres out of 100 are under the plough. In the neighbourhood of Aylesbury, the average crops of Hay have not exceeded 5 cwt. per acre, instead of from one to two tons; and many meadows have not been cut at all, from the shortness of keep in the pastures. Many have been relying on rain in July and August, to mow in September and October, but this is now out of the question. The object of this communication is to invite discussion and information as to the best mode of supplying dairy stock with food, in lieu of Hay, during the winter, in a district where green crops, and especially Turnips, are scarcely known. On my farm of 300 acres, about seven acres sown with White Carrots and Mangold Wurzel, have wholly failed; and my Turnips, although they came up abundantly, and are untouched by the fly, are dying away in the present drought.—*A Farmer.*

FARMERS' CLUBS.

Darlington Farmers' Club.—This Club held their monthly meeting on Monday last, at the offices of Mr. Thos. Dixon, Land Agent, their Honorary Secretary, when there was a pretty good attendance of members present. The subject under discussion was The most beneficial Time for Reaping Wheat and other Corn, and the profitable Mode of Cutting and Securing it. Henry Chapman, Esq., the Chairman, introduced the subject, and said, that having formerly himself been a pretty extensive farmer, for a good many years, more particularly in Derbyshire, he had had opportunities of observing the cutting and harvesting of Wheat under different circumstances, and he was decidedly in favour of cutting Wheat before being fully ripe, as by that means a finer sample is obtained, as well as having the crop cut with less waste; but although he was an advocate for reaping Wheat before being fully ripe, yet he did not recommend cutting it very raw; for although a brighter sample was by that means obtained, yet he was strongly of opinion that it yielded a less quantity of flour; not, however, having himself made any experiments in proof of this position, he merely gave it as his opinion.—The Secretary then said, that from the experience he had had, he considered it judicious to cut Wheat a little earlier than what has been generally practised, as by that means not only is a brighter and better sample obtained, but if the crop is broken down, as is sometimes the case, it could be cut up much cleaner in a raw state than if fully ripe; the straw is also of a better quality, and in a wet harvest both the corn and straw stand the weather much better than when cut ripe. And in support of this position he mentioned the circumstance of the Wheat on the farm on which he was resident in the wet and unsound harvest of 1816 being cut in a very raw state, and the consequence was, that when all the neighbouring farmers' Wheat was completely sprouted in the stook, by the long-continued wet weather, the Wheat on this farm was comparatively sound; and in the succeeding winter and spring, when other farmers of the neighbourhood sold their Wheat in Darlington Market at 22*s.* per sack, the Wheat from this farm sold for 28*s.*; and he believed that the principal, if not the only reason, was that the Wheat on this farm having been cut in a much earlier stage of ripeness than the rest of the neighbourhood, it was not so easily affected by the weather. He then read some extracts from the "Quarterly Journal of Agriculture," detailing some experiments made by Mr. J. Hannam, of North Drighton, near Wetherby, by which it was clearly shown that it was injurious to allow Wheat to stand until fully ripe before cutting, and that the best period for cutting Wheat was from 10 to 14 days before fully ripe.—An animated discussion now ensued both as to the proper period for reaping and the best mode of cutting and securing the crop, and several members considered hooding the stooks of great service in securing the Grain from the ill effects of the weather; whilst, on the other hand, several others were of opinion that, if properly stooked, it was as well without hooding. As to the best mode of reaping, it having been up to this time almost the universal practice in this neighbourhood to cut Wheat with the sickle, there was no advocate for deviating from the old practice; but as regarded the proper period for reaping, the members present were unanimous in opinion that it is best to cut Wheat in a rather raw state—perhaps a week, at least, before being fully ripe.

Miscelianeous.

Cultivation of the Turnip.—The land is ploughed up as early as possible in the autumn, and receives one, two, or more ploughings, as opportunity offers. In the early part of the winter such portions as require draining are thoroughly drained with pipes of two inches' bore, having the opening heart-shaped—the widest part of which is placed downwards—upon the top of which stone is placed to about three inches in depth, consisting principally of small flints and pebbles, picked from the surface of the land; as soon as the land is sufficiently dry it receives two deep cross-ploughings early in the spring, is rolled and harrowed until a fine tilth is produced, and is then formed into ridges, or small stetches, 37 inches each in width, which is thus effected:—A straight furrow is first ploughed, and a double-breasted plough is then used, having a marking instrument attached, which consists of a small straight tough pole fixed at right angles from the beam of the plough by means of a hook, and placed as far back as possible, so that it does not derange the operation of the plough whilst working; at the end of this stick an iron is fixed exactly the width of two of the intended ridges, which is connected diagonally by a chain with the whipple-tree of the horse; this, as the plough proceeds, marks out the next furrow, occupying the space of two ridges. The work thus proceeds followed by a similar plough, or by the ploughman returning, who, by passing his plough down the middle of this space, divides the stetch of 6 feet 2 inches into two smaller ones of 37 inches each, the marker still defining the distance at which the plough should be held; the ridges being formed, are ploughed off with four furrows to each, and then every fifth ridge is drawn out to enable the manure to be carted on without injuring the form of the ridge. After the manure is carted on, at the rate of 16 loads of 40 bushels each, the ridges are then ploughed by four furrows, leaving a small bank in the centre so as to divide the ridge into two spaces for the manure, which, from being partially decomposed, is easily spread in this double furrow; the land is then ploughed at four furrows to each ridge, and the manure being covered in, is rolled and harrowed, and is again rolled with a light roller. The Turnips are then drilled—two rows upon each ridge 11 inches apart, at the rate of 4 pints to the acre, thus standing at alternate spaces of 11 inches and 26 inches between the rows. As soon as the Turnips appear, they are singled out by boys and women at 15 inches apart, and are left standing diagonally with each other; they are then carefully and deeply hoed with a heavy hoe, and the furrows are kept clean with the horse-hoe, but the Turnips are invariably set out by hand and never by the hoe, the deep hoeing that is given being considered a main point in the system over and above that pursued with the common light Turnip-hoe; and the singling by hand is assisted by a small measured stick 15 inches in length, enabling the children employed to set the Turnips out regularly and diagonally, so that when finished they stand thus ·.·.·. In the months of November and December the Turnips are all pulled, avoiding the use of hooks or cutting instruments for trimming them, merely wringing off the tops and dislodging the greater portion of the earth attached to the fibres without cutting them. The Turnips are then carted to the respective fields where they will be required for winter use, and one moiety of them is left in the field for using there; those left are put into heaps of about 40 bushels each, are thatched over with straw, and the earth shovelled up and placed round the heaps to the top, which ends in a point. Those taken from the field are carted to the headlands of other fields where they will be required, which are principally those upon which Wheat was grown in the preceding year after Clover. The old hurdles used for folding are then selected for this purpose; one is placed first at the end across the space to be occupied by the Turnips, and two more are put at right angles, forming a space made by the double row of hurdles, in which the Turnips are placed, taking care to cart them when dry, and adding more hurdles lengthwise until sufficient space is obtained, and the Turnips are disposed of in rows about 7 ft. wide and 4 ft. in height. The Turnips are then protected by the earth being dug up and placed on both sides, leaving air-holes at about 4 or 5 feet distance, level with the surface of the land, which may be formed as the work proceeds by introducing small faggots tied loosely, or by any other mode, leaving the sides of the whole open so as freely to admit air, and extending across from side to side, which is of especial importance towards the preservation of the Turnips, as they might otherwise get into active fermentation, which when it takes place frequently destroys the greater part of them. The top of the heap is then covered with Barley-straw and thatched, and thus the Turnips are preserved from injury by frost and game during the most severe weather, and will remain in excellent condition until May following, very little impaired by keeping. The application of them is by feeding them upon the eddishes, and upon the land upon which they are grown by sheep in fold. The Turnips are all sliced, and the sheep are regularly fed in troughs, having a new fold every day, and with from ½ lb. to 1 lb. each of oil-cake per day. The sheep, for the most part, consist of lambs of the last year, and cost from 16*s.* to 20*s.* each—these in the following spring are shorn and sent to market, and produce from 30*s.* to 32*s.* each; the fleeces from the half-bred Leicesters weighing each about 6½ lbs., and selling from 12*d.* to 16*d.* per lb.—*Mr. Baker, on Essex Farming, in the English Agricultural Society's Journal.*

African Guano.—The guano, in the state in which it was received, formed a moist chocolate-brown powder, intermixed with numerous particles of a whitish substance. It possessed no urinous odour, but smelt strongly of ammonia. On examination under the microscope, no crystals of any kind could be detected in it; but it contained numerous remains of plants, partly in a state of decomposition, but still exhibiting a green colour, and globules of starch in the cells, likewise brown and white feathers, fragments of egg-shells and fish-bones. The aqueous solution was of a light reddish-brown colour, was strongly ammonical, and deposited on slow evaporation an abundant crop of crystals of the triple phosphate of ammonia magnesia. On adding nitric acid to the filtered liquid, an abundant flocculent brown precipitate subsided, which consisted of humic acid and extractive. The insoluble portion was of a light sandy-yellow colour. On boiling with solution of potash and precipitation of the filtered solution with hydrochloric acid, a light-brown flocculent substance subsided, which amounted to 5·50 per cent. This was first regarded as uric acid, but on further examination it proved to contain but slight traces of that ingredient, and to consist of a substance allied to humic acid. To determine the absolute amount of ammonia, one of the ingredients on which the value of guano chiefly depends, a weighed portion of the guano in its normal state was analysed according to the method described by Varrentrap and Will, and afforded 9·70 per cent. The other ingredients were determined in the usual way, and according to the results of analysis, 100 parts of the guano in question consist of—

Volatile salts, as oxalate of ammonia, chloride of ammonium, carbonate of ammonia, and combustible organic matter, containing 5·50 per cent. humic acid, uric acid and extractive	32·80
Water	27·13
Ammonia	9·70
Phosphates of lime and magnesia	22·37
Insoluble residue in nitric acid, consisting of sand .	0·61
Alkaline salts, chiefly phosphates, muriates, and small quantity of small sulphates (chiefly potash).	7·08
	100·00.

From the above examination, it is evident that the African guano differs considerably from the Peruvian and Chilian, *i. e.* that it has been more exposed to the decomposing influences of atmosphere and water than either of those kinds, and tends rather to confirm the

slaves of Fritzsche, Ilgen and Boussingault, Girardin and Didard, that the Peruvian guano is in a state of fossilisation. The most remarkable guano hitherto analysed is that described by Fritzsche,* whose investigations, as far as we are aware, have hitherto remained unnoticed in this country. We need, therefore, not apologise for giving a brief abstract of them in this place, more particularly as they will prove how requisite it is that the agriculturist, before purchasing guano, should have a sample submitted to analysis by some competent chemist. Fritzsche describes the guano submitted by him to examination as a dry coarse powder, in which some large compact masses occurred of a yellowish-brown colour. The compact pieces from which the powder had originated were distinctly composed of superposed strata, seldom horizontal, but most frequently compressed and undulate. The strata are of two kinds, one of a brownish-yellow colour, and consisting principally of urate of ammonia; the other of a blackish-gray or dark brown colour, and formed principally of clay. Both layers alternate with each other irregularly, their relative proportions varying considerably. The argillaceous strata are of a more compact nature than those of the urate of ammonia. All the layers of clay are coated with a whitish rind, which cannot be readily washed off with water. This coating consists of urate of ammonia, and proves beyond a doubt that the guano in question has acquired its present state through the agency of water. Feathers, vertebræ, and fragments of other fish-bones occur frequently, as well as remains of plants and some seed. The guano had a strong urinous smell and a faintly saline taste. 16 oz. of the pulverulent mass in its moist state afforded on solution in caustic potash and precipitation with muriatic acid, 7 oz. 2 drs. of a yellowish-brown coloured crystalline hydrate of uric acid = 37 per cent. anhydrous uric acid. 200 grs. of a compact fragment, with very few seams of clay, gave, on being similarly treated, 118 grs. or 59 per cent. of anhydrous uric acid. The residue of these experiments consisted for the greater part of clay, which readily subsided, probably on account of the earthy phosphates contained in it. From the occurrence of so few organic remains, and from the interposition of the argillaceous masses between the layers of urate of ammonia, it is evident that the guano in question cannot have been deposited by the birds in the state in which it occurs at present; the coating of urate of ammonia, which adheres so firmly to the seams of clay, decidedly shows that water must have acted some part at the formation of this deposit. Let us suppose a clayey shore, which is flooded at high tide and left dry at ebb, and behind it a lake to which the tide rises, and flocks of sea-birds which visit the coast at the time of low water; all the requisite conditions are given. Fish and other marine animals, left by the tide, attract the birds, which, in taking their food, at the same time loosen the soil. Meantime a tropical sun dries and breaks up the soil; the tide returns, and carries these loose masses of clay, and the excrements deposited on them, into the basin. In their progress a process of lixiviation takes place; the lighter organic remains, which have not time to subside, are carried away by the effluent water, while the heavier urate of ammonia and fragments of clay subside. At some depth the bottom of the basin is not disturbed by the flood, and here a solution of urate of ammonia may be formed, which subsequently, on drying, covers the layers of clay with a white coating, and serves to unite the pulverulent urate of ammonia and loose clay. The amount of soluble constituents in the guano (20 per cent.) is not opposed to this view, for if the urine of these birds is secreted, like that of serpents, in a concrete form (containing, therefore, solid urate of ammonia), it would be impossible for the salt water to deprive it of much of its soluble constituents during its transfer, and its rapid subsidence in the basin would prevent subsequent extraction. Now it is quite evident that the African guano has been exposed to entirely different conditions to that of the Peruvian just described; for while this contains the enormous amount of 59 per cent. uric acid, scarcely traces of it occur in the former, it having undergone total decomposition. Moreover, the amount of soluble constituents in the African Guano (above 60 per cent.) entirely excludes all idea of its having been subjected to any such lixiviating process as that supposed by Dr. Fritzsche. We may, in conclusion, venture a few words with respect to the comparative value of the African guano as a manure. This depends, first, on the amount of phosphates, and secondly, on that of the ammonia, or substances capable of affording that ingredient. But it is also evident that the state in which the nitrogenous compounds are contained in the manure must be of some importance, i. e. whether they exist in the form of ammonia, as is the case with the guano submitted by us to analysis, or in the state of uric acid.† It is probable that this African guano would prove extremely stimulating to vegetation at first, but that its power would soon be spent, unless previous to its employment it were mixed with some substance capable of fixing the ammonia, such as gypsum or charcoal, as recommended by Boussingault and Payen; while that containing uric

* "Bulletin de l'Acad. de Petersbourg." t. No. 6.

† "The value of a manure depends, therefore, on the proportion of nitrogenised organic matter, and especially in relation to the non-nitrogenous organic substances, and lastly, on the decomposition of the quaternary substances being gradually effected, and so keeping pace with the progress of vegetation." And again, "A manure entirely decomposable into its soluble and gaseous products in the course of a single year will be capable of producing as great an effect on the first crop as five times the quantity of another manure which would require five years for its ultimate decomposition, but then the latter will furnish useful products during a period five times longer."—*Payen and Boussingault in "Ann. de Chim. et de Phys.," t. lii. pp. 67 and 70.*

acid would, from the slow decomposition of this substance, prove for a long time a constant source of nitrogen proportionate to the growth of the plants.—*Chemical Gazette.*

Employment of Boys as Farm Labourers.—Gangs of boys from 10 to 15 years of age are constantly employed, at wages from 4*d.* to 8*d.* each per day; with every 10 or more boys a man is placed, who is made responsible for their properly executing the work, and also for their application. Narrow hoes are used in preference to wide ones. The Wheat, Beans, and Peas first receive attention, and are all thoroughly hoed and weeded at a cost of about 3*s.* to 4*s.* per acre; the boys also dibble in the Mangold-seed, and single the plants of both that and the Turnips ready for the hoe, weed all the Lent corn, each being furnished with a glove, and then assist in making the hay, shaking it out with their hands without using forks; the smallest are then released for the month of harvest, to follow gleaning, and the largest are all kept to various work, such as hoeing and cleaning the Turnips, and assisting in the harvest-work as required, but always accompanied by the man. As the season advances, the pulling and carting of the Turnips again occupies them, and it is only during the depth of winter that the smallest are not employed. Frequently two or three gangs of from 10 to 15 in each gang are at work; the light hoeing is thus executed at a less cost than could be effected by men, and the boys are at the same time taught early to work and to become industrious.—*Mr. Baker, on Essex Farming, in the English Agricultural Society's Journal.*

Notices to Correspondents.

Rural Chemistry. By Edward Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, has been reprinted from the *Gardeners' Chronicle*, with additions, and may be had of all booksellers, price 4*s.* 6*d.*

Books.—*Ebor.*—Low's "Elements of Practical Agriculture." The subject of dibbling Corn shall be attended to.

Chinese Oat.—*N. N. P.* asks for information as to where he can obtain the Chinese Skinless Oat.

Churn.—*Anon.*—Next week.

Dairy Vessels.—*Hacienda.*—We have no experience on the deleterious effects of zinc on milk, but we believe the assertion to which you allude to be true. The acids formed or existing in milk are solvents of the metal. We do not know the medicinal properties of sea-water.

Decrease in Value from Inundations.—*Mallow.*—We cannot answer your question in our ignorance of the amount of risk to which you are subject. In certain districts bordering on the Severn, at one stage of its course, an inundation involving the total destruction of the crop once in ten years is calculated on; here the effects of liability to such risks obviously affects the value of property simply to the extent of 1-tenth.

Drains.—*H. C.*—Use soles to your draining-tiles; about 9inch arvensis, see Home Correspondence.

Old Pastures.—*W. C.*—Decidedly the best way of breaking them up is by paring and burning. This could be done in spring before Turnip seed-time. You will not otherwise be able to get the land reduced sufficiently for the proper cultivation of the crop. You are certainly judicious in taking a crop of Turnips as the first after Grass. If you pare and burn you may grow Clover on the third year as you propose. The flesh of the alpaca is spoken of as resembling venison.

Potatoes.—*Suburban Farmer.*—If the stalks or haulm are green you cannot cut them off without injuring the crop.

Seed-Wheat.—*J. E.*—The Childham Wheat is a prettier Wheat in the berry than Mr. Morton's, but so far as our somewhat limited experience of it goes, it is not so productive a variety. Shirreff's Hopetoun is a white Wheat and we should greatly prefer it to the Red Lammas. Will you favour us with your name and address?

Turnips.—*Brassica.*—They can only be propagated by seed.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Sept. 9.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3s 10 to 4s 0	Best Downs & Half-breds	3s 10 to 4s 0
Best Short Horns	3 8 3 10	Best Long-wools	3 8 3 10
Second quality Beasts	3 0 3 4	Ewes and second quality	3 0 3 4
Calves	3 4 4 0	Lambs	3 8 4 4
Pigs	3 4 4 4		

Beasts, 2917; Sheep and Lambs, 23,070; Calves, 151; Pigs, 270.

The number of Beasts to-day is much smaller than last Monday, yet there is a fair average supply; the trade is rather brisker, and in some instances the very best qualities are making 2*d* per 8 lbs advanced price; as a general statement of the market, however, we cannot alter our last quotations; the second quality Beasts find more purchasers than of late, and make a little better price. There are a few less Sheep, but still a very large supply; there are, however, more buyers in the Market than of late, which causes the trade to be a shade better; still, there is not a quotable advance in the price. There is a little more demand for Lambs. Pork-trade is rather better.

FRIDAY, Sept. 13.

The supply of Beasts to-day is large, and trade very dull at fully 2*d* per 8 lbs lower than on Monday; as 10*d* is quite the top price for the best qualities, and many good Beasts are sold at 3*s* 8*d* per 8 lbs. The supply of Sheep continues about the same, but owing to the improved state of the dead markets since Monday, the best qualities are making a little more money, but not quite 2*d* per 8 lbs advance; middling quality is still difficult to dispose of. Veal-trade is a little more lively, but it is difficult to make over 4*s* per 8 lbs of anything. Pork-trade continues pretty good.

Beasts, 957; Sheep and Lambs, 8320; Calves, 338; Pigs, 330.

4*l.* West Smithfield.

HOPS, Friday, Sept. 13.

About 500 pockets of the new crop of Hops have arrived at Market, for the most part diseased and unripe, and consequently are not much in demand; what few have been sold have realised about as follows:—Farnhams, 10*l* to 10*l* 10*s*; Mid Kents, 9*l* 10*s* to 10*l* 10*s*; Weald of Kents, 7*l* 7*s* to 9*l*; Sussex, 7*l* to 8*l* 8*s*. We expect picking will be general on Monday next, and that the Market will be well supplied during next week. The duty is estimated at 130,000*l.*, and no doubt prices will be high.

Farebrother & Smith, Hop-Factors.

HAY.—Per Load of 36 Trusses.

SMITHFIELD, Sept. 12.

Prime Upland Hay	90s to 110s	Clover	100s to 120s	Straw	28s to 30s
Inferior „	80 90	„ New	100 120		
New Hay „	80 100				

Jones Cooper, Salesman.

CUMBERLAND MARKET, Sept. 12.

Superior Old Hay	100s to 110s	Superior Clover	120s to 128s		
Inferior „	80 100	Inferior „	90 100	Straw	28s to 30s
New Hay „	— —	New Clover	— —		

Jones, Baker, Hay Salesman.

WHITECHAPEL, Sept. 13

Prime Old Hay	95s to 105s	Old Clover	120s 130s		
Inferior „	80 95	New Clover	100 115	Straw	28s to 30s
New Hay	— —	Inferior „	— —		

WOOL.—British, Friday, Sept. 13.

Business continues to be a good deal of business done in our English Wool market. The prices of Fleece Wools remain unaltered. We think the demand for Combing Wools a little better, but for low short Wools, particularly white, there has been a good demand.

	Per lb.		
Leicestershire Wethers	1*l* 0*d* to 1*l* 1*d*	Southdown Hoggets	1*l* 2*d* to 1*l* 3*d*
Dry Hoggets	1 1 1 2	Kent Fleeces	1 1 1 2
Scots Down Fleeces	1 0 1 1		

COVENT GARDEN, Sept. 14.—The supplies of both fruit and vegetables have been very large and considerably exceed the demand; trade is consequently dull. Some fine specimens of Pine Apples are in the market, and hothouse Grapes are also good and abundant. There is no difference in the price of Melons since our last report. Peaches and Nectarines still continue good, and are sufficient for the demand. Of Plums there are some good samples of Coe's Golden Drop. Green Gages are almost over for a season, and Orleans are very scarce. Of Damsons there is abundance. Figs are offered at nearly the same price as last week, and very little alteration has taken place in that of either Apples or Pears. Among the former we noticed some good samples of Ribston Pippin, Hawthornden, and Emperor Alexander, and among the latter were fine looking specimens of Williams's Bon Chrétien, Marie Louise, and Louise Bonne (*of Jersey*). Siberian Crabs are now in the market, as are also Walnuts, which are selling at from 10*s.* to 28*s.* per bushel. Filberts are well supplied. Of Vegetables there is abundance. Cauliflowers bring nearly the same price as last week; they have somewhat improved of late. Broccoli is tolerably plentiful, and Cabbages and Coleworts are abundant. French Beans are good, and still continue sufficient for the demand. Onions are plentiful. Capsicums and Mushrooms are not altered in price since last week. Carrots and Turnips of good quality are abundant, as is Celery. Lettuces, Endive, and other kinds of Salading are plentiful. We observed amongst Cut Flowers, Combretum purpureum, Gladiolus puttacinus, Gardenia radicans, Agapanthus umbellatus, China Asters, Amaryllises, Camellias, Heaths, Pelargoniums, Fuchsias, Verbenas, Carnations, and Roses.

FRUITS.

Pine Apple, per lb., 2*s* to 6*s*	Morello Cherries, per hf.-sv., 1*s* 6*d* to 2*s* 6*d*
Grapes, Hothouse, p. lb., 1*s* to 3*s* 6*d*	Currants, per hf-sieve, 2*s* 6*d* to 3*s* 6*d*

Spinach, per sieve, 1*s* 6*d* to 2*s*	Chervil, per punnet, 2*d* to 3*d*
Leeks, per bun., 2*d* to 3*d*	Chilis, per 100, 1*s* 6*d* to 2*s*

MARK-LANE, Monday, Sept. 9.

The supply of English Wheat this morning from the home counties was small, and taken off slowly at the prices of this day se'nnight: Foreign met a moderate retail demand on the terms of last Monday, being rather over those of the forced sales made at the close of Friday's market.—English Barley must be written 1*s.* lower: Foreign meets a slow sale, and barely maintains late rates.—Beans fully support our quotations.—White Peas are unaltered. Grey and Maple 1*s.* cheaper.—The Oat trade is firm, and last week's prices readily obtained.—The top price of Flour is reduced to 44*s.*

FRIDAY, Sept. 13.

The little English Wheat fresh up since Monday has been taken off at the prices of that day; in foreign there is very little business doing, but its value is fully supported.—Barley, Beans, and White Peas, maintain our late quotations, Maple and Grey are the turn cheaper.—The quantity of Oats offering ex ship being very small, dealers refrain from purchasing, and prices may be considered unaltered.

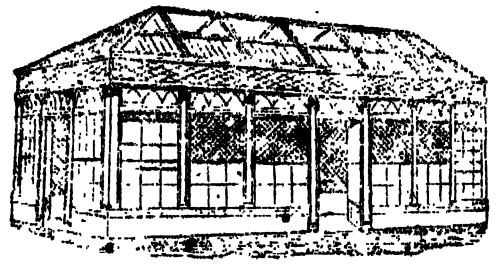
TO NURSERYMEN AND SEEDSMEN.

TO BE SOLD, BY AUCTION, by Mr. STEPHEN, (without reserve), on MONDAY, the 23d of SEPTEMBER, 1844, at 12 o'clock in the forenoon, on account of the decease of Mr. RICHARD TODD, the late proprietor, all the Shrubs, Forest Trees and Plants, Shop and House-Fixtures, Greenhouse, &c., situate on the Leicester-road, Loughborough, in the county of Leicester.



TO GARDENERS, NURSERYMEN, AND OTHERS.

TO BE LET, with immediate possession, within 20 miles of London, a small NURSERY, and PUBLIC-HOUSE doing a good business. The Nursery is well stocked with choicest American Shrubs, Fruit, and other Trees; is situated within a few minutes' walk of a railway station. Every particular can be procured by application to Mr. KENNAN, 4, Great Russell-street, Covent Garden; and Mr. NEAL, Nurseryman, Wandsworth Common. No person without capital need apply.

VERY ELIGIBLE FARM.

TO BE LET on LEASE, from Michaelmas next, Forest Lodge (otherwise Llosccod), situate from Brecon, and 15 from Merthyr; containing 700 Acres of Land of the best quality, and in excellent condition. It has a Threshing machine and a Corn and Bone-mill, all worked by water; extensive Barns and Cattle-sheds, a very large Piggery, a Steaming-house, Liquid Manure Tank, and all requisites for the scientific cultivation of the Farm. An excellent Sheep-walk of 700 acres can be attached, if desired. The whole is well situated as to roads.—Apply to Mr. DRAYCOTT, Glanusk, Lenny Bridge, Brecon; or to Mr. LAWES, Rothamsted, near St. Albans.

HORTICULTURAL BUILDING & HEATING by HOT WATER.

J. WEEKS and Co., ARCHITECTS, &c., Gloucester-place, King's-road, Chelsea, Hothouse-Builders, and Hot-water Apparatus Manufacturers, beg leave to inform the Nobility and Gentry, that their business, which has been extensive throughout the country for many years, is entirely confined to the BUILDING OF HORTICULTURAL ERECTIONS of every description, and the HEATING of them by HOT WATER.

CONICAL and other BOILERS of all sizes; their largest consumes but a small quantity of fuel, only requiring attention once in 10 hours, and will heat a range of Forcing-houses 300 feet in length.

Their improved plan of BOTTOM-HEAT FOR PITS, by means of an open trough under the bed, is now being universally adopted.

References may be had, and their works seen at most of the Nobility and Gentlemen's seats in the country, nearly the whole of the London Nurseries, and a great variety of Horticultural Erections and Hot-water Apparatus, Models, Plans, Estimates, &c., at their Horticultural Manufactory, Gloucester-place, Chelsea, near Sloane-square.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree, without the aid of pipes or flues. S. & C. have also to state that, at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen-apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in the country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Greenhouses or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

GUANO (GENUINE PERUVIAN & BOLIVIAN), ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PEYTON, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL. 47, Lime-street, Sept. 13, 1844.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or water-side premises; smaller quantities may be had at the warehouses, 24 and 25, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to JAMES CLARK, 24, Billiter-street.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to a most extensive system of adulteration. Orders addressed early to the Works, 28, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual of most Chemists and Seedsmen.

*** Beware of being imposed upon by inefficacious imitations.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Sept. 7, 1844:—

Bones	p. ton	£4	10s. 0d	Nit. of Potash	p. cwt. £1	4s. 6d

WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

GYPSUM, &c.—Pure Gypsum (Sulphate of Lime) for Compost Heaps, Urine Tanks, Stables, &c.; also Sulphuric Acid, Guano (foreign and Potter's), Rape Cake and Rape Dust, and all other Manures, may be had of the Undersigned.

Synopsis of Prices, and mode of use, on application.

MARK FOTHERGILL, 30, Upper Thames-street.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also, those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5A, Hawley-road, Kentish Town.

HATCHER'S BENNENDEN TILE-MACHINE, Manufactured and Sold only by COFTAM and HALLEN, Engineers, Agricultural Implement Makers, &c., 2, Winsley-street, Oxford-street, London.

This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With this amount of labour, the product of a day of 10 hours is as follows, viz.:—

1 inch diameter of Tile,	11,000	1½ inches diameter of Tile,	5,600
1¼ ,, ,, ,,	9,000	2½ ,, ,, ,,	3,200

The Machine is movable down the drying-sheds, so that it requires no extra boys to carry the Tiles, nor are shelves required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Cranbrook, Kent. No charge made for Patent dues or licence. The purchase of the Machine includes free use of it.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water-courses. In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. BAILEY DENTON has arranged with an eminent London Mathematical Instrument Maker to make them in any number required. Price 30s.

This Level is as accurate as a spirit-level, and so simple, that the workman unable to read can use it with facility. When closed it forms a 5 feet staff.

Orders addressed to Mr. BENTON, Land Agent, 9, Gray's Inn-square, London; or to Mr. CHADWICK, Wakefield, Yorkshire, will insure a perfect instrument.

WHEAT SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial, it being much more powerful, and free from adulteration, so lately complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

Testimonial to Brain's Guano Manure.—"5A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have used Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation: (it is not adulterated, and can always be depended on, being of uniform composition.)—(Signed) JOHN MITCHELL and FREDERICK FIELD, Analytical Chemists, of the Royal Polytechnic Institution, London."

Also, BRAIN'S highly-concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1s. 6d. per quart bottle, with full directions for use, (enough for 80 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade. THOS. J. CRODDON, 8, Ingram-court, Fenchurch-st., London.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, ARCHITECTS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, in agricultural districts, many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet), with printed directions for applying them.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Grueber & Co., 11, Mancaty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland, and Newcastle-on-Tyne, Messrs. John Ritson and Son; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKIBBIN'S Improved SHEATHING, BOILER, RAILWAY, and other FELT.

BURBIDGE AND HEALY'S COOKING APPARATUS, combining Sylvester's Patents.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the Public, both as regards strength of material and workmanship; in fact, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the Apparatus; and B. & H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 130, Fleet-street.

GLASS MILK PANS, patronised by the ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—Glass Milk Pans have been long and extensively employed in Germany, which led to their introduction in England. The chief advantage is cleanliness, as they require neither scouring nor hot water after use, but are readily rinsed in cold or tepid water.—White Glass Transparent Milk Pans, to hold 8 quarts, 5s. each; Green Glass ditto, ditto, 3s. 6d. each; Ditto, to hold 4 quarts, one-third less in price; Cream Vases, to hold 8 quarts, or 4 quarts, same price as the above; Six-inch Butter Plates, 1s. 6d. each; Condensing Covers, 2s. each; all large sizes, at 1s. 1d. per lb. Manufactured by APSLEY PELLATT, Falcon Glass Works, Holland-st., Blackfriars-road; also sold at the Baker-street Bazaar.

PELLATT'S CONDENSING PROPAGATORS.—The prevention of drip and a moist atmosphere are desiderata in striking cuttings, &c. The above simple invention, by filling the trough with water, alternately evaporates and condenses, and when once filled seldom requires replenishing. Price:—8 inches diameter, 10d. each; 6 inches ditto, 1s. 4d. each; 7 inches ditto, 2s. each. All larger sizes, 1s. 4d. per lb.—Manufactured by APSLEY PELLATT, Falcon Glass Works, Holland-street, Blackfriars Road; and also Sold at the Baker-street Bazaar.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam-ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 8, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

NATIONAL TESTIMONIAL TO MR. ROWLAND HILL, ESQ., AUTHOR OF THE PENNY POSTAGE.

Under the management of the

CITY OF LONDON MERCANTILE COMMITTEE ON POSTAGE.

SIR GEORGE LAUREN[illegible], Bart., Chairman & Treas.

The Committee have the pleasure of announcing to the [illegible] that in consequence of the request very generally made to [illegible] from all parts of the country, they have determined to keep [illegible] the Subscription to the above Testimonial for a few weeks [illegible].

The Committee are further encouraged to [illegible] of their labours by the success which has hither[illegible] they feel confident that their object only requires [illegible] generally known to insure the active co operation [illegible] of society, for all have derived benefit from the sche[illegible] with is the Author

The Subscriptions already received in London amount to £3000. Further sums to the extent of £500 have been actually collected in various parts of the country, and returns have yet to be received from 200 places, at which 2000 Subscription Cards are yet in circulation.

In the subjoined List will be seen the names of places at which Collections have been made and remitted to London The inhabitants of Cities Towns, and Villages not there mentioned, are entreated to aid the exertions in aid of this National acknowledgment of the services of one who has laboured for and established a National benefit

Where no Committee has been, or can be formed, Subscriptions forwarded by post office orders or otherwise, to Mr. George Wansey, Solicitor, 7 Tokenhouse-yard, the Secretary of the London Committee, will be acknowledged, and he will also supply Subscription Cards and afford every information required.

By order of the London Committee, G. WANSEY, Secretary.

London, Sept 13th, 1844.

Amount previously advertised £3415. 8s. 7d.

A few copies of the Second Edition of this Catalogue may be had at the reduced price of 1s. 6d. each.

LITERARY LEAVES; or, Prose and Verse, By DAVID LESTER RICHARDSON.

2 vols. 8vo, Second Edition, price 12s.

"We strongly recommend this second and enlarged edition. We can easily imagine how such writings as these, appearing from time to time in the Indian journals, must have gratified the English residents, since even here, in the midst of lions and new books, we can pore over the leaves with unmixed pleasure."—*Atlas.*

"His poetry derives, from his unfeigned attachment to home, a very touching beauty. Most persons who have been long absent from the place of their birth know how delicious is the feeling with which it is approached. Mr. Richardson describes this feeling with exquisite truth and tenderness.... Whatever forms of nature challenge his preference, he views them all with a poetical eye, and paints them in his verses with vividness and fidelity. We should be glad to see the poetry of these volumes detached from the prose, and sent into the world alone. It has sufficient character in it to depend on its own vitality; and we venture to predict that it will live."—*Sunday Times*

"The essays afford some exquisite reading. We can with perfect confidence refer every man of literary taste to these volumes, which we consider an elegant and valuable contribution to the literature of our country."—*Indian News.*

"The poems are largely impregnated with Nature's best and holiest feelings. They are utterances of the writer's own heart, and they reach the hearts of his readers. They leave an impression which will not be easily or speedily effaced. The diction is in keeping with the sentiments; it is at once accurate and graceful The same observation applies to the author's prose writings."—*Observer.*

ADVERTISEMENTS IN THE MONTHLY JOURNAL OF MEDICAL SCIENCE, Edited by Dr. CORMACK. Few Periodicals present such advantages to the Advertisers of Medical and Scientific Publications, Works in General Literature, Medical Practices, Chemical Products, Pharmaceutical Preparations, the Prospectuses of Life Insurance Societies, &c. The circulation is large, and has from its commencement gone on steadily increasing in Great Britain, Ireland, India, America, and the Continent of Europe It is taken in by many General News-rooms, by almost all of the Reading Clubs and Medical Societies in Town, and by a very large proportion of Country Practitioners, in England, Scotland, and Ireland, to whom, from its cheapness, and comprehensive character, it is specially adapted. Advertisements inserted in this Journal must be seen by many thousands of the most select class of readers.

*** For the SCALE OF CHARGES, and all other particulars, reference may be made to Mr. Churchill, Princes-street, Soho, London; Messrs. Machachlan, Stewart, and Co., South-bridge, Mr. Jack, Niddry-street, Messrs. Hasthill and Son, Waterloo-place, and Mr. Seton, Head of the Mound, Edinburgh; Messrs. Fannin and Co., Dublin; most News Agents in Great Britain; and Messrs. Fortin, Masson, et Cie, Paris.

Printed by WILLIAM RICHARDS, of No. 6, York-place, Stoke Newington and Farnham Mostyn Evans, of No. 7, Church-row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-street, in the precinct of Whitefriars, in the City of London; and published by them at the Office, No 4, Charles-street, in the parish of St. Paul's, Covent-Garden, in the said county, where all Advertisements and Communications are to be addressed to the Editor.—Saturday, September 14, 1844.

OPEN TO ALL ENGLAND.

THE UXBRIDGE EXHIBITION for DAHLIAS, FRUIT, and FLOWERS, will take place on Monday, September 23, at the Uxbridge Nursery, where Cleopatra, the finest and most constant yellow Dahlia in existence, may be seen growing; it has been pronounced useful and fit for a stand of six by the best judges. The Stock will be divided into 20 shares, and let out dry at 10 guineas, if all the shares are subscribed for by the 20th of November; otherwise in plants at 10s. 6d. in May, 1845. (Dahlias in classes.) Blooms of the above Dahlia may be seen at Mr. Nutting's, 45, Cheapside.

J. KERNAN begs to announce the arrival of his large and carefully-selected Dutch, Capo, and other Bulbs of every description.

Finest named Hyacinths, old favourites, from 6s., to 12s. and 18s. per dozen.

Double red mixtures, different shades, 2s. 6d. per dozen.

Double blue, 3s. 6d. per dozen.

Double white, 3s. 6d. per dozen.

Single, each colour, as above, 2s 6d. per dozen.

Early Tulips, Narcissus, Jonquils, Anemones, Ranunculus, Iris, Ixias, Amaryllis, with all the new Lilies and good Herbaceous Plants, hardy and greenhouse, worth cultivating.

J. K. has also to offer, of this season's saving, some very choice seed—

From the finest named Calceolaria, 2s. 6d. per packet.
" " Cineraria, 2s. 6d. "
" " Heartsease, 2s. 6d. "
" " Geranium, 2s. 6d. "
Scarlet Phlox Drummondii, 6d. per packet.
Schisanthus Hookeri, 6d. "
Intermediate Stock, 6d. "

By sowing the above this autumn a season will be saved.

With many other good Biennials and Perennials. Also, Myatt's new Deptford Pine Strawberry, Myatt's British Queen do.; Prince Albert do., Lady's Finger do., Keen's Seedling do., Old Pine do., &c. &c.

Dulley's Scarlet Admirable Rhubarb, the very best for early forcing Giant Asparagus and Sea kale plants. Rivers's new Catalogue and Amateur's Rose Guide.

White Clover, Rape, Winter Tares, Rye, and Italian Ryegrass, for early green food. Catalogues may be had on application. All Mr. Rivers's Dwarf and Standard Roses may be ordered through J. K.

Curtis's and other new Budding and Pruning Knives.

4, Great Russell-street, Covent Garden, Sept. 1844.

J. T. WILLMER, King's Road, Chelsea, by Appointment Florist to Her Majesty, begs to inform his Friends and the Public that his Carnations and Picotees are now ready for sending out, catalogues of which may be had on prepaid application containing a postage stamp.

IMPORTED BULBS IN GREAT VARIETY.

WILLIAM CLARK, 25, Bishopsgate-street Within, London, respectfully informs his friends of the arrival of the above in very sound condition, and solicits early orders. Also may be had, strong plants of Princess Alice Maude Strawberry, Myatt's British Queen and Deptford Pine.

LILIUM LANCIFOLIUM. — Flowering Bulbs of these most beautiful LILIES to be had at the following low prices: Lancifolium album . . 5s. each.
" punctatum . . 3s. "
" speciosum . . 2s. "
of W. J. Nutting, Seedsman, 45, Cheapside, London.

Seed from the best varieties of IXIAS and SPARAXIS, at 2s. 6d. per packet.

NEW CARNATIONS, PICOTEES, AND PINKS.

MESSRS. N. and B. NORMAN'S CATALOGUE of SHOW VARIETIES can be had on prepaid application.—Ball Fields, Woolwich.

BRAGONDALE HORTICULTURAL ESTABLISHMENT.

JOHN BELL begs to inform his Friends and the Public, he has just received his Importation of DUTCH HYACINTHS AND OTHER BULBS, direct from Haarlem. Catalogues of which may be had at the Nursery, or his Seed Warehouse, 3, Exchange-street, Norwich.

MESSRS. MARNOCK & MANLEY beg to inform their friends and the public that they are now sending out their DUTCH BULBS, which have arrived in exceeding fine condition. Catalogues may be had on application.

Nursery, Hackney, Sept 19, 1844.

CARNATIONS, PICOTEES, PINKS, AURICULAS, ALPINES, AND POLYANTHUS.

JOHN HOLLAND, Florist, &c., Market-place, Middleton, near Manchester, Lancashire, respectfully informs his Friends and the Floricultural Public that his extensive and choice collection of the above Florists' Flowers are now ready for sending out, Catalogues of which are now ready, and may be had on prepaid application.

Market-place, Middleton, September 19.

THE FINEST DUTCH HYACINTHS and OTHER BULBS DIRECT FROM HAARLEM.

YOUELL AND CO. beg to inform their Friends and the Public they have just received their first Importation of the above in the finest possible condition, Catalogues of which can be had on application. They are enabled to offer "the finest Double or Single Blue, Red, White, and Yellow Hyacinths at 18s. per dozen."

Very fine ditto . . . . . 12s. per doz.
Fine ditto . . . . . 6s. "
And other Roots at equally moderate prices.
The Finest Norwich Black Baguet Tulips, 2s. each.
P S.—Bulbs will be added as compensation for long carriage.

YOUELL AND CO. are now sending to any part of the United Kingdom the undermentioned highly-desirable Plants, full particulars of which will be found in their former Advertisements.

FUCHSIAS—per post free.
12 Extra Fine varieties, 12s., the Selection left to Youell & Co.
12 ditto ditto 21s., the Selection left to the Purchaser, *comprising most of the new varieties sent out this season.*
50 Fine varieties . . 40s., the Selection left to Youell & Co.
50 Extra Fine ditto . . 60s., the Selection left to the Purchaser.
VERBENAS—per post free.
12 Extra fine Varieties, 6s., the selection left to Youell & Co.
12 Ditto " 10s., the selection left to the purchaser.
PANSIES. [Sent postage free.]
12 Fine Show Varieties, by name . . 10s. per dozen

FINEST SHOW PINKS, by name, 12s. per doz.
N.B. All Orders above £2 are delivered carriage free to London or Hull, or plants added to compensate for the same.

☞ For Particulars of their Extensive Collection of CARNATIONS and PICOTEES, (Catalogues of which may be had on application) see their Advertisement of last week.

Great Yarmouth Nursery, Sept. 19, 1844.

EARLIEST STRAWBERRY in CULTIVATION. —Strong Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 20s. per 100. As an Early Strawberry, it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season. Also Plants of the "British Queen," "Deptford Pine," "Prince Albert," and all the leading kinds. To be had of Messrs. Warner & Warner, Seedsmen, 28, Cornhill, London.

CAMELLIA JAPONICA.

ROBERT LAWSON, Esq., of Tiverton, intends disposing of his stock of Camellias, which he has collected at much expense, and successfully cultivated for many years. They are in the highest state of health, and most abundantly set with blooming buds. Mr. L. disposes of them solely in consequence of their having become too large for his conservatory. They are as follow:—

			£	s.	d.
Reticulata,	from 7 to 8 feet in height,	a very fine specimen, quite healthy and green	10	10	0
Imbricata,	from 7 to 8 feet in height,	do.	8	8	0
"	" 3 to 4 "		1	10	0
Eximia	" 7 to 8 "	a magnificent plant	7	7	0
Chandlerii	" 6 to 7 "	a fine plant	5	5	0
"	" 3 to 4 "		1	10	0
Lady Hume's Blush	6 to 7 "		4	4	0
Double White	6 "		5	5	0
"	" 5 to 6 "		3	10	0
"	" 5 "		2	10	0
Invincible (Gray's)	5 to 6 "		3	3	0
Fordii	" 4 to 5 "	very fine	4	4	0
"	" 2 to 3 "		1	1	0
Double Striped	5 to 6 "	fine	2	10	0
Anemoneflora Alba	4 to 5 "		2	10	0
Speciosa	" 4 to 5 "		2	2	0
Woodsii	" 4 "	fine	2	10	0
Warratah	" 4 to 5 "	fine	2	2	0
Florida	" 4 to 5 "		2	10	0
Corrallina	" 3 "		1	5	0
Lawsonii	" 3 "	new	1	10	0
Colvillii	" 3 "		0	10	6
Donkelaerii	" 3 "		0	10	6
Insignis	" 6 to 7 "	very fine	2	10	0
Eclipse (Penn's)	6 to 7 "		2	2	0

The Prices affixed are for the seperate plants, of which not less than 3 can be taken together. If the whole are taken in one lot a considerable reduction will be made. Mr. Lawson will be happy to show them, or give any further particulars that may be required.—Tiverton, Sept. 20th, 1844.

MR. LYNE'S NEW SEEDLING GERANIUMS.

WILLIAM E. RENDLE has much pleasure in offering to the Nobility, Amateurs, and Trade the following new varieties of GERANIUMS raised by P. E. Lyne, Esq., the entire stock of which he has succeeded in obtaining.

		£	s.
Lyne's Princess Alice	each of	1	1s.
Lyne's White Perfection	"	1	1
Lyne's Imogene	"	1	1
Lyne's King of Saxony	"	1	1
Lyne's Redworth	"	1	1
Lyne's Confidence	"	1	1
Lyne's Sappho	"	1	1

The whole set as above for six guineas. The usual discount to the Trade.

"Princess Alice" has received two seedling prizes in London. "White Perfection," first prize at Torquay, and the Gold Medal at Plymouth. "Imogene" is described in the *Chronicle*, June 24th, 1843. They all possess most desirable properties, and can be highly recommended as being first rate flowers.

W. E. R. has been induced to offer the above at prices considerably lower than usually obtained for such valuable varieties, in hopes thereby to meet with a more extensive demand. Descriptions can be obtained on application.

Orders will be executed in strict precedence. Plants will be delivered in October next. Reference or remittance required from unknown correspondents. Plants will be added to compensate for carriage.—Union Road Nursery, Plymouth, Sept. 20.

TRUE HIGHLAND PINE.

JAMES GRIGOR, Nurseryman, Norwich, begs to call the attention of the Land Proprietors of England to this very desirable variety of Pinus sylvestris, which has been raised from seeds collected on the mountains of Strathspey, and of which he has strong plants ready to be sent out. For introducing this tree Messrs. Grigor, of Torres and Elgin, were awarded several premiums by the Highland and Agricultural Society of Scotland; and in that part of the country this Pine is rapidly superseding the common soft-wooded variety. For all economical purposes its chief merit consists in the hardness and durability of its wood; hence it is much sought after at present for railway sleepers. Pictorially considered, or as a landscape ornament, it rivals even the Cedar of Lebanon. Sir Walter Scott describes it as assuming much of "the bold and contorted figure of the Oak;" and in the last No. of the *Quarterly Review* it is recommended as a fit tree to be planted in churchyards and cemeteries.

Strong plants in pots, such as rabbits and hares will not destroy . . . . . 6d. each.
Ditto, not in pots, 18 inches high . . 30s. per 1000.
Ditto " 15 " . . 20s. "
Ditto " 1 foot high . . 15s. "
Ditto " 3 years old . . 10s. "

J. G. would recommend all who require them to furnish themselves immediately with these Pines, and to plant them forthwith. Spring planting is exceedingly hazardous; and when followed by such a season as was experienced during the commencement of the present summer, the young trees are sure to be killed.

Cedrus Deodara raised in the open ground, being the strongest plants yet offered in England, 10s each. Araucaria imbricata, Pinus excelsa Laricio, Austriaca, &c &c on reasonable terms.

ROSES.

WOODLANDS NURSERY, Maresfield, Near Uckfield, Sussex. WOOD & SON have the honour to announce that they are now issuing GRATIS, on application, their newly arranged CATALOGUE OF ROSES, containing a full and comprehensive description of all the most popular varieties, in addition to the novelties that have appeared this season.

Catalogues may be had at Edinburgh, of Mr. R. I. M'Intosh, 12, Catherine street. Woodlands, September 20.

SHRUBBY CALCEOLARIAS, PANSIES, &c.

H. MAJOR, of Knosthorpe, near Leeds, begs to intimate that he can supply healthy plants of the best twelve varieties of Calceolarias he sent out for the first time last spring, for 24s. post-free. Plants procured now will bloom early in the spring.

H. M. has plants of most of the leading sorts of PANSIES; the following 24 select kinds he offers for 24s post free—viz, Bridegroom (Major's), Bridegroom (Widnall's), Black Prince, Black Bess, Conservative, Carion, Eclipse, Glory of Knosthorpe, Maid of Milan, Oliver Moonshine, Queen of Whites, Success, Unique, William Tell, Mrs. Harcourt, Sulphurea elegans, Exquisite, Regulator, Miss Batty, Lady Alice Peel, Azurea, Leader, Hector, and Black Dwarf. The present is a proper time for planting Pansies for a spring bloom. Additional plants will be sent to compensate for carriage by hamper.

Packets of Select Pansy-seed, saved from most of the leading varieties, and from several superb Seedlings, at 2s. 6d and 5s. per packet.—A remittance or an unknown correspondents is respectfully requested.

Mr. M. will next spring have to offer a new set of splendid Seedling Calceolarias, raised this year, as well as several Seedling Pansies, among which will be found an excellent white (superior to any out), a creamy white, one with clear white centre and delicate blue border, and one similar in character to his unrivalled "Bridegroom," but of different colours. Also a few choice Carnations and Picotees, correct in name, sort, and colour.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4s. per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. Corbett's, late Mr. Barron's, Italian and Foreign Warehouse, 16, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

DUTCH HYACINTHS.

WARNER AND WARNER, Seedsmen, No. 28, Cornhill, London, respectfully inform the Nobility and Gentry their Dutch Flower-roots have arrived in superior condition, consisting of the choicest and newest varieties. The Bulbs are unusually handsome and large, at moderate prices. Catalogues forwarded by post on application.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs. WARNER & WARNER, Cornhill, London, after the 7th September.

SPLENDID NEW HEAVY-EDGED PURPLE PICOTEE, WOOD'S "PRINCESS ALICE."

JOHN WOOD begs to announce that the stock of this superb flower is now ready for sale at 15s. per pair, postage included. It has gained the following prizes:—At Cambridge Florists' Show, 1843, it was the 1st seedling, and the 1st heavy-edged purple; at the same Show, in 1844, it took the premium prize, beating all the Picotees exhibited. At Huntingdon, 1843, it was 1st seedling and 1st purple Picotee; at the same place, 1844, it was 1st, 2d, 3d, and 4th, excluding every other flower. At Peterborough, 1843, it was the 1st seedling, took 1st pair of purple, and was in the best stand of six Picotees; in 1844, at the same Show, it took the 1st pair, and was again in the 1st stand of six.

J. W. flatters himself that this statement precludes the necessity of farther comment. Plants of the above may also be had of HURST and M'MULLEN, 6, Leadenhall street.

J. W. has a few pairs of that splendid Pink Garratt's "Queen of Roses," for sale, at 7s. 6d. per pair; his Catalogue of Carnations, Picotees, &c., may also be had on prepaid application; and those about to commence growing, he will supply as follows, if left to his selection.

CARNATIONS AND PICOTEES.

		£	s.	d.
50 pairs good sorts, one pair of each		3	0	0
25 do. do. do.		1	10	0
24 do. fine show flowers		2	0	0
12 do do.		1	0	0

PINKS.

25 do. do. do.		0	10	0
24 do. fine show flowers		0	18	0
12 do. do.		0	9	0

N.B.—Remittances must accompany the orders of unknown correspondents.—Nursery, Huntingdon.

Mr. HOYLE'S NEW SEEDLING GERANIUMS.

WILLIAM MILLER respectfully announces to the Nobility, Gentry, Amateurs, and the Trade, that he has purchased the entire stock of the following superb SEEDLING GERANIUMS raised by G. W. HOYLE, Esq., of Guernsey, viz.

1844—Titus	each—	£3	3s.	0d.
Pompey		3	3	0
Champion		2	2	0
These three for six guineas.				
1843—Unique		1	1	0
Queen of England		1	1	0
Claude		1	1	0
Sarah Jane		1	1	0
Amelia		0	10	6
Majestica		0	10	6
Rosalia		0	10	6
Flora		0	10	6
General Pollock		0	10	6
These nine for five guineas.				

The entire set 10 guineas, with a discount of 20 per cent. to the Trade. A remittance must accompany the order from unknown correspondents.

Titus received a seedling prize at Chiswick, June, 1844; Pompey, Champion, and Unique were pronounced by Professor LINDLEY, in the *Gardeners' Chronicle* of June 29, 1844, to be "three flowers of good substance, size, and variety;" and Mr. Glenny, in *Gardeners' Gazette* June 22, 1844, says, speaking of the Geraniums at the Chiswick Fête—"Mr. Hoyle had by far the best lot there; Pompey was the best of them, and Titus next." Blooms of the others were likewise exhibited at the June Fête, Chiswick, 1844, and attracted very extraordinary attention, and were universally admired. On the whole, the above varieties, for substance, roundness of form, and general excellent qualities, are among the best ever offered to floriculturists. Printed Lists, with full descriptions, can be had on application. To commence sending out plants in October.

W. M. has been supplied by Mr. Hoyle with some choice GERANIUM SEED, which he saved from his own beautiful Seedlings, and the newest and best varieties sent out by other growers. Sealed packets of 100 seeds, 12s.; do. of 50 seeds, 7s. Also, Hybridised Seed, saved from his own extensive collection of Pelargoniums; packets of 100 seeds, 10s.; of 50 seeds, 6s.

Providence Nursery, Ramsgate.

INGA PULCHERRIMA. (Figured in "Paxton's Magazine of Botany" for August, 1844.)—Fine Plants of this extremely elegant and beautiful Exotic, with most of the other new and rare Plants of the season, may be obtained of the undersigned, at the following low prices:—

Inga pulcherrima, 7s. 6d.	Habrothamnus elegans, 15s.
Achimenes picta, 10s. 6d.	Tremandra Hugelii, 10s. 6d. to 21s.
Æschynanthus Horsfieldii, 7s. 6d.	Veronica speciosa, 5s. to 15s.
Amycia zygomeris, 7s. 6d.	Erica elegans, fine and healthy, 15s., 24s., and 30s. per doz.
Clerodendron splendens, 10s. 6d.	squamatum, 5s.
Hindsia, or Rondeletia longiflora, 15s.	Drymonia punctata, 3s. 6d.
Epacris campanulata roses (the finest selected from 1000 seedlings), 7s. 6d.	Phlox Van Houttei, (flowering-plants), 2s.
	Spiræa Reevesiana, 5s.
	Viburnum cotonifolium, 3s. 6d.

Also the following, in collections

100 Cape Ericas of 100 distinct sorts, (including many fine sorts) 5l.	(including Campanulata roses) 21s.
12 Epacrises of 12 distinct sorts,	12 Azalea indica, of 12 distinct sorts, (including fulgens) 21s

THOMAS JACKSON, Kingston Nursery, Surrey, Sept. 20.

FUCHSIA "PRINCESS ALICE."

G. H. BUNNEY having purchased the stock of the above splendid Fuchsia—which was awarded the first Prize at the Royal Botanic Society's Exhibition, Regent's Park, in June last, when it was very much admired for its profusion of fine thick flesh-coloured and pink flowers, and fine habit of plant; it also was awarded the first Seedling Prize at the South Essex Exhibition in Wanstead Park, on Sept. 4, the only place exhibited—plants of the above Fuchsia will be sent out early in October at 5s. per plant, with a discount to the trade when six plants are taken; likewise 4 Seedling Cinerarias.

BUNNEY'S KILLEAN, 3s. 6d., fine red, gained 1st Prize at the Royal Botanic Society, Regent's Park, June Show, and Wanstead Park.

BUNNEY'S DIANA, 3s. 6d., white, deeply margined with purple, fine broad petals, and excellent habit.

BUNNEY'S NERO, 2s. 6d., very dark-blue, fine habit.

BUNNEY'S VESTA, 2s. 6d., light blue, very distinct colour.

Or the above 4 for 10s.

MIMULUS SPLENDENS, 2s. 6d., fine scarlet profuse bloomer, of fine shrubby habit, was awarded a Prize at the Royal Botanic Garden, July Show. All orders for the above, addressed to G. H. BUNNEY, Maryland Point Nursery, Stratford, Essex, (late of the Kingsland Nursery) will be punctually attended to.

CHOICE FLOWERS AND PLANTS IN POTS.

WM. IVERY, FLORIST, &c., Peckham, near London, begs to inform his Friends and the Public that he is ready to supply the undernamed Plants, which he can with confidence recommend.

AZALEA LATERITIA FORMOSA, bright red, 21s. to 31s. 6d. each. "A Certificate of Merit was awarded to Mr. Jas. Ivery, of Betchworth, having large flowers, clean and bright in colour, and expanding freely."—DR. LINDLEY in *Gard. Chron.*, *May* 25.

AZALEA COCCINEA SUPERBA, bright scarlet, good shape, and free bloomer, 15s. each; Azalea delicata, bright pink, good shape, and abundant bloomer, 15s. each.

CINERARIAS.—Beauty of Wonham, very large white beautiful eye and dwarf habit, 5s.; tricolor, white and pink, brown eye, compact flower, 5s.; Nosegay, purplish blue, good petal, and noble truss, 5s.; Washington, very large crimson, good petal, 5s.; Captivation, white ground, with beautiful mazarine purple tips, gained first Prize at the West Kent June Exhibition, 5s., Criterion, mazarine blue, beautiful white centre, gained first Prize at Dorking May Exhibition, 7s. 6d.; Red Rover, bright crimson, beautiful prolific bloomer, 5s.; Fanny Elsler, white crimson tips, prolific bloomer, 5s.; Pickwick, bright purple large flower, and fine shape, 3s. 6d.; Compacta, small, white, and beautiful round flower, 5s.

The whole set of Seedling Cinerarias, 2l. 5s.

The following CINERARIAS can be recommended as good:—Ivery's Beauty of Syston, bronzy purplish blue, fine winter flowering var., 3s. 6d.; Emperor, 2s.; Pride of Peckham, 2s. 6d.; Regulata, 2s.; Delicata, 1s. 6d.; Regina Victoria, 2s. 6d.; Triumph, 2s.; Rival King, 1s.; Imperial Blue, 1s.; Royal Blue, 1s.; Iveryana, 1s. 6d.; Princess Royal, 1s. 6d.; Queen Victoria, 1s. 6d.; Exquisite, 3s. 6d.; Wee Pet, 3s. 6d.; Henderon's Azurea, 1s. 6d.; Pilot, 1s. 6d.; Unique, 1s. 6d.; Magnet, 1s. 6d.; Prince of Oldenburgh, 3s. 6d.; Sombre Agreeable, 3s. 6d.; Eclipse, 1s. 6d.; No. 7, 1s. 6d.; Enchantress, 1s 6d.; Compact Blue, 1s. 6d.; Bell's Decora, 1s. 6d.; Good's Compacta, 3s. 6d.; Gaines's True Blue, 1s. 6d.; Prince Albert, 1s. 6d; May's Queen of May, 2s. 6d.; Youngii, 1s. 6d. Good varieties from 5s. to 12s. per doz. Fine Cineraria Seed, 2s. 6d. to 5s. per packet.

Fine PETUNIA, noticed in "Calendar of Operations," *Gard. Chron.*, Sept. 14. Ivery's Pet, 1s. 6d. to 2s. 6d.; Magna Charta, 1s. 6d. to 2s. 6d.; Reliance, 1s. 6d. to 2s. 6d.; Ovid, 1s. 6d.; Prince Albert, 1s. 6d. to 2s. 6d.; Kentish Beauty, 1s. 6d.; Enchantress, 1s.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND-MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. In Tin, 1l. 10s each; or with Copper Box and Tube, 1l. 15s. each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. COTTAM and HALLEN, 2, Winsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers in the United Kingdom; or from the Inventor, by letter to his address, inclosing a Post-office order for the amount.—RICHARD SMITH, Upper Hall, near Droitwich, Worcestershire.

HOTHOUSES, CONSERVATORIES, &c., made and fixed Complete in all parts of the Kingdom. One, two, and three-light Cucumber and Melon-Boxes and Lights of all sizes kept ready for immediate use, packed and sent to all parts of the Kingdom; warranted best material. Two-light Boxes and Lights complete, from 1l. 8s. Garden-Lights made and glazed from 1s. per foot, at JAS. WATTS' Sash Manufactory, Claremont-place, Old Kent-road. *** Reference given.

EXTIRPATION of the MEALY-BUG, THRIPS, &c.—These pests to Gardens can be readily and effectually extirpated without injury to the most delicate plants, by HERRMAN'S VEGETABLE DILUTIUM, sold in bottles at 5s., 10s., and 20s. each, free of carriage to all parts of Great Britain.—Address, with a remittance, either to SAMUEL HERRMAN, Romsey, Hants, or Messrs. MARNOCK and MANLY, Nurserymen, &c., Hackney, who are the sole London Agents.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

Sales by Auction.

TO GENTLEMEN, BUILDERS, NURSERYMEN, & OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed to Sell by Public Auction (under a bill of sale), on the premises, Sussex Nursery, Loughboro'-road, Brixton-road, on Monday, 30th September, 1844, at eleven o'clock, the whole of the NURSERY STOCK, consisting in choice Evergreens and Flowering Shrubs, Standard and Dwarf Roses; also two newly-erected Greenhouses, Frames, about 2000 Greenhouse Plants, a quantity of Rock Work, Utensils in Trade, &c.; may be viewed prior to the sale. Catalogues may be had on the premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone.

FREEHOLD NURSERY-GROUND, ST. ALBAN'S, HERTS.

MESSRS. PROTHEROE & MORRIS have received instructions from the Executors of the late Mr. Robert Fullwood, the mortgagee, to submit to public competition at the Auction Mart, Bartholomew-lane, on Thursday, 3d October, 1844, at One o'clock, THE KEY FIELD NURSERY AND NURSERY PREMISES, adjoining the town of St. Alban's, comprising a comfortable and convenient Dwelling-house and Shop, fronting the High Road from St. Alban's to London, and about six acres of very productive Nursery and Garden Ground. The whole Freehold and Land-Tax redeemed, and immediate possession may be had. The Premises were late in the occupation of Mr. David Watson, who for many years and up to the period of his death carried on the business of a Nursery and Seedsman. May be viewed at any time, and particulars had at the principal Inns in the neighbourhood, at the Auction Mart, of J. S. Story, Esq., Solicitor, St. Alban's; of George Drew, Esq., 186, Bermondsey-street, Borough; and of the Auctioneers, Leytonstone, Essex.

BUNNEY'S FINAL SALE.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, BUILDERS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor (in consequence of the Lease having expired), to submit to Public Competition by Auction, on the Premises, Kingsland Nursery, Balls Pond-road, on MONDAY, Oct. 7, 1844, and following days, at Eleven o'Clock each day without reserve, the whole of the valuable NURSERY STOCK, consisting of FRUIT and FOREST-TREES, a considerable quantity of EVERGREENS, AMERICAN PLANTS, STOOLS, &c. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their Grounds; also the Trade, from its excellence, and comprising an excellent collection of Ghent AZALEAS, MAGNOLIAS, RHODODENDRONS, &c. May be viewed prior to Sale. Catalogues may be had on the Premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone.

ISLINGTON NURSERY.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, and Others.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor to submit to Public Competition, on MONDAY, 14th October, 1844, and following days, at 11 o'clock, (in consequence of the ground being required for building,) a portion of the valuable NURSERY STOCK, consisting of about five thousand Belgian Azaleas, in 40 fine varieties; several thousands fine Hybrid Rhododendrons, well furnished with bloom buds; Green and Var. Hollies, Chinese and Siberian Arborvitæ, about five thousand Laurels, with a fine assortment of Fruit and Forest Trees, Flowering Shrubs, &c.

May be viewed prior to the Sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, American Nursery, Leytonstone.

SIX DAYS' SALE OF VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition, by Auction, at the American Nursery, Leytonstone, Essex (about one mile from the Railway Station, Stratford), on Monday, 21st October, 1844, and five following days, at 11 o'clock, (to close Executors' accounts), the celebrated NURSERY STOCK, consisting of the choicest kinds of Fruit and Forest Trees, fine Evergreens, Ornamental, Deciduous, and American Plants, of every variety, in considerable quantities, and lotted to suit every description of purchasers. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their grounds, from its having many rare specimens that are only to be found in first-rate collections (also of the Trade, from its excellence), and comprising several thousands Azaleas, Rhododendrons, Ledums, Andromeda, all in fine condition for potting, being well furnished with bloom buds.

N.B. The ground is proverbial for safety of removal, the mould adhering to the roots. May be viewed prior to the Sale. Catalogues, One Shilling each, returnable to purchasers, may be had of the principal Seedsmen in London, at the Auction Mart, and of the Auctioneers, Leytonstone, Essex.

VERY ELIGIBLE FARM.

TO BE LET on LEASE, from Michaelmas next, Forest Lodge (otherwise Lloscood), six miles from Brecon, and 15 from Merthyr; containing 700 Acres of Land of the best quality, and in excellent condition. It has a Threshing-machine and a Corn and Bone-mill, all worked by water; extensive Barns and Cattle-sheds, a very large Piggery, a Steaming-house, Liquid Manure Tank, and all requisites for the scientific cultivation of the Farm. An excellent Sheep-walk of 700 acres can be attached, if desired. The whole is well situated as to roads.—Apply to Mr. DRAYCOTT, Glanusk, Lenny Bridge, Brecon; or to Mr. LARGE, Bassel Down House, Swindon.

TO MARKET GARDENERS.

TO BE LET at EALING, six miles and a half from London, a GARDEN of 11 ACRES, with House, Stable, &c. Possession may be had immediately.—For particulars apply at Mrs. ROBERTS's, on the Green, at Ealing.

TO AGRICULTURISTS.—Any person wishing to enter into a Large Farming Business, 30 miles from London, and near a Railway Station, at Michaelmas next, may hear of a very favourable opportunity by addressing a letter to A. B., Penshurst, Kent.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHERWEN, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollinson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to a most extensive system of adulteration. Orders addressed early to the Works, 29, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual of most Chemists and Seedsmen.

*** Beware of being imposed upon by insidious imitations.

NEW PLANTS.

MESSRS. VEITCH AND SON have now ready for sending out the two undermentioned beautiful New Plants, viz. :—

HINDSIA VIOLACEA. Strong plants at 63s. It is figured by Dr. LINDLEY, in the "Botanical Register" for August last, who there says—"The Hindsia violacea is one of the finest things obtained from South Brazil. It has been imported by Messrs. Veitch and Son, of Exeter, who received for it the Large Silver Medal at the Horticultural Society's Garden Exhibition in May last. It will doubtless prove a very easily cultivated Greenhouse Plant; and is certainly unsurpassed in beauty by blue-flowering shrubs."

CLITORIA PULCHRA. Strong plants at 42s. This plant was exhibited at Chiswick, in May, under the name of Centrosema species, and received the Knightian Medal. See Report in *Gardeners' Chronicle* for May 28. It is figured in "Paxton's Magazine" for July last.

Messrs. V. and Son have also to offer the following fine plants, viz.:—

Achimenes picta	Gardenia Sherbournea
Allemanda grandiflora	,, tetrasperma
Barbacena squamata Veitchia	Gesneria polyantha
Clerodendron lævifolium	Gloxinia Cartonii
,, splendens	Hindsia longiflora
Cyrtoceras reflexa	Inga pulcherrima
Echites atropurpurea	Luxemburgia ciliosa
,, hirsuta	Passiflora actinea
,, splendens	Pentas carnea
Gardenia Rothmannia	Thunbergia chrysops, &c. &c.

N.B.—Messrs. V. and Son's General Catalogue can be had on application.—Exeter, Sept. 19, 1844.

The Gardeners' Chronicle.

SATURDAY, SEPTEMBER 21, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

SATURDAY,	Sept. 28	Royal Botanic	4 P.M.
TUESDAY,	Oct. 1	Horticultural	3 P.M.
FRIDAY,	Oct. 4	Botanical	8 P.M.

COUNTRY SHOW.—TUESDAY, Sept. 24, Chichester Horticultural 2 P.M.

THE Vine, say English GRAPE-GROWERS, likes a moist rich soil; so give it plenty of manure, of horseflesh and swineflesh, and other good things; make it grow rank, fill your houses with strong long rods, and when you have got them—cut them off again. The Vine inhabits one of the hottest countries beyond the tropics; so, say English Grape-growers, plant it on the outside of a house, where the soil is coldest, if you want to force it. It fruits in perfection in the burning soil of Syria and Sicily. When the spies came to Moses out of the land of Canaan, "they came unto the brook (valley) of Eshcol, and cut down from thence a branch with one cluster of Grapes, and they bare it between two on a staff." But our climate gives our Vines deluges of cold water, or we warm their roots by fermenting stable-litter, whose influence hardly extends beyond the surface of the ground; and, strange as it may seem, by such means English gardeners get the finest Grapes that are known beyond the limits of Vine cultivation in the open air.

It would, therefore, seem that we are right, and that the peculiarities of our climate render necessary this departure from the natural habits of the Vine. But seeming may not be reality; and it is quite possible that if gardeners grow admirable Grapes by violating every principle that one would think should guide them, they may grow them still better by attending to those principles. We cannot seriously believe that the Vine loves the coarse and watery food we give it: all that we can imagine is that it will bear it.

"Some years since," says Mr. Hoare, in his recent work on the Vine,* "I received a bundle of Vine-cuttings from one of the most celebrated Vineyards in Spain. They were the entire growth of the year, as each had a portion of the preceding year's wood attached to it. The longest shoot measured 8½ feet, but the average length was about 8 feet. The wood was perfectly cylindrical, of the closest texture, and *almost as hard as heart of Oak*. The buds were large, prominent, and highly symmetrical, *and stood out in bold relief on the sides of the canes.*"

Now, who ever saw such wood in England? and how can we expect to have Grapes of Spanish excellence without wood of Spanish quality? And hence, for such and other reasons, which are urged with full knowledge of his subject, Mr. Hoare maintains that the system of English Grape-growing requires to be changed.

We are not prepared to go so far as he does; for he should have shown to what size the bunches of Grapes had arrived which were obtained from his Spanish Vines, before he accepted them as conclusive proof that such hard short-jointed wood is indispensable to good Grapes. But we think that his arguments deserve very serious attention, and cannot fail to lead to most important changes in the cultivation of the Vine. What we most doubt is, whether the hard-wooded short-jointed Spanish wood produces large bunches of juicy berries as well as Grapes of high flavour. If it does not, our own *unprincipled* practice will still prevail to a great extent. Mr. Hoare seems to be of opinion that it did or would.

As we cannot change our sun and air, we must try to mend our ways. Since frost and snow will come, and cold rain will lodge in our Vine-borders, in spite of all our dislike to it, we must oppose those disadvantages by skill. Mr. Hoare, considering, it may be presumed, that houses are sufficiently well heated, and Vines as well pruned and managed as they can be, directs attention to the Vine-border—to the badness of which, in one respect or another, he attributes all the disasters of Grape-forcing; and his little book is written principally to advocate this side of the question. That he will have offended prejudices by his views is certain; that the clans Do-little, Do-nothing, and Stand-still, will ridicule his book, we doubt not. But he need not be alarmed; although these once were formidable bodies, and ruled the land of gardening, they are now but broken men, without a head to lead them. We happen to know that Mr. Hoare's statements are the result of actual experience, and that all which he recommends has been repeatedly and cautiously examined experimentally. For many years his observations have been conducted with the utmost care. By depositing a great variety of substances in excavations made for the purpose, mixing them in different proportions, changing them in almost every conceivable way, planting Vines in them, and then, after a year or two, pulling the plants up again, and then examining their roots minutely, he has been able to ascertain what the substances are which the Vine roots select to feed upon. And by repeating this process for many years, he has arrived at the conclusions which have led to the recommendation contained in the work before us. Need we say more to insure to them the attentive consideration of sensible men?

We shall not pretend to repeat the arguments upon which Mr. Hoare grounds his opinions; we shall only say that they are for the most part satisfactory to us. Our previous observations would, however, have no practical application if we did not mention what the materials are which he proposes to substitute for the ordinary Vine-borders. "These are *broken bricks, lumps of mortar, charcoal* and *bones*. The three first should be reduced to the size of a hen's egg, or thereabouts. Larger or smaller fragments will do, but when they are about this size they are better calculated to retain the requisite degree of moisture in connection with the greatest possible extent of surface. The bricks should not be too hard burnt, because their porosity is thereby lessened. Old mortar should be preferred to new, when it can be procured. The bones may either be broken into fragments or deposited whole, and the fresher they are the better. Any description of bones will do, provided they are those of animals arrived at maturity, and are therefore of a solid and lasting nature. Such as have marrow in them should be broken asunder, that the interior surface may be available to the roots of the Vines; and the lighter and more porous the charcoal is, the better will it answer the intended purpose. The whole of these materials should be used in equal proportion, measure for measure, and should be well mixed together. But before this is done, the bricks, mortar, and charcoal *should be well soaked in urine, and then used immediately.* And as these substances convey to the roots of Vines an extraordinary supply of nutriment in a highly concentrated form, a small quantity in bulk, in proportion to that of common soil, will be amply sufficient to support a single Vine for a long series of years."

In addition to this, he protests most strongly and sensibly against planting Vines that are to be forced in borders exposed to the open air. Surely nothing can be more obviously wrong than this. What Mr. Hoare says is very true. The roots of Vines in a cold border do not move because the branches leaf. On the contrary, for months the leaves are supported by the sap contained in the buds and branches, while the roots are still asleep; that sap becomes exhausted; nothing replaces it, for the benumbed roots cannot stir; and then, when the fruit should swell off and repay the expense incurred in Vine-borders and Vine-houses, it shrivels and shrinks—produces verjuice instead of sugar.

But this subject is capable of more extended application, in Mr. Hoare's opinion, and we must revert to it next week.

SINCE our observations upon the value of SULPHATE OF IRON for purifying offensive collections of decaying matter were printed (p. 555), some further information upon this subject has reached us.

Sulphate of iron seems to fulfil every condition that can be required of such an agent, where the material to be sweetened is inclosed in receptacles of some kind, the contents of which do not escape. But where the offensive matter is acted upon by water, which is continually escaping through drains or floating off by sewers, it is to be expected that a considerable waste of a material so soluble as this iron salt will take place; for it is obviously impossible to calculate with any sort of accuracy how much putrid fluid has to be operated upon in a given time, or the strength of such fluid.

For this reason it has been proposed by M. Siret, a French gentleman having great experience in the purification of drains and sewers, to unite the very soluble salt of iron with some material which will prevent its rapid dispersion, and he has found that the following mixture answers the purpose perfectly. Take

Sulphate of iron	. .	200 kilogrammes.*
Sulphate of zinc	. .	25 ,,
Vegetable charcoal	. .	10 ,,
Plaster of Paris	. .	265 ,,
		500 ,,

Blend these substances thoroughly, and then add water to them till they form a solid mass. Of such a mass 75 kilogrammes, or about 165 lbs., placed at the mouth of a sewer, will keep 500 yards sweet for a fortnight; "the fluids gradually dissolving themselves as they pass over it, and thus becoming pure. At least such is the result of the experiments at Meaux, in the Brassat sewer, which takes the drainage of the leather-dressing factories. The use of plaster of Paris, which holds together the disinfecting powders, does not decompose them; on the contrary, it excites rather than diminishes their sweetening effects."

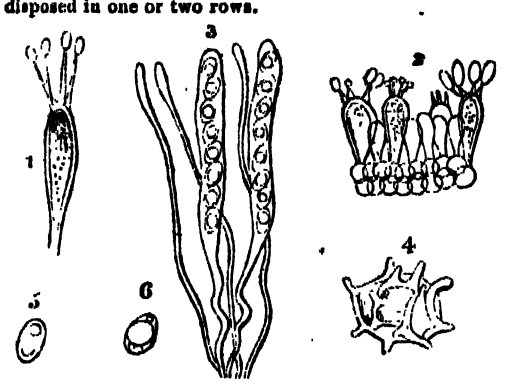
We do not understand the necessity of adding a salt of zinc to the "Siret cake," and are not without fear as to its effect upon manure, which it may render less fit for vegetation than without it. The experiment is, however, worth the making, and also, considering the vast interests involved in such an inquiry, the varying, according to circumstances. A man must have very little ingenuity who cannot perceive to how many places besides sewers and drains the "Siret cake" is applicable, not merely in the country, but in London. Parish officers especially should, without loss of time, turn their attention to the application of some such processes as those of Messrs. Schattenmann and Siret, to purposes, the necessity for which need not be more particularly alluded to.

WASPS.

SOME of your correspondents, as well as other parties, have not been so successful as they might have been in applying spirits of turpentine to the destruction of wasps' nests. I observe that one person says he found the wasps alive on the morning after he had applied the turpentine. If he refers to the former accounts, describing successes, he will see that 24 hours is the time specified before the wasps are killed. If he had waited till the following morning he would probably have insured success. The attack may be rendered more powerful by stuffing tow or cotton-wool into the bottle, well soaked with turpentine. Where the destruction of the nest is the only object, I should very much like to have it ascertained whether anything further is necessary than to inject the turpentine, and block up the hole. From what I have observed of the nests I have examined after 36 hours from the time I had applied the turpentine, they were so much filled with dead wasps, and there was such an evident tendency to incipient mouldiness and decay about them, that I should suppose the whole would have become a mass of corruption in a day or two more; and that all the maggots in the cells must then inevitably have perished. When the nest is taken out before it becomes corrupt, those maggots which have assumed the pupa state readily hatch; of which I have at this moment ample experience in a nest I took up a fortnight ago, and have kept in an outhouse for purposes of observation. The wasps are flying in and out of the door by hundreds. The best way of preserving these interesting objects is to dig up a cubical mass of the earth, and carry it away with the nest in the middle: which can be done where the soil is sufficiently tenacious. The soil may be wetted with a weak solution of glue, which will bind it firmly together when dry. The nest may then be exposed on two opposite sides, leaving the other two to support the roof. A portion of the outer case must be removed, for the purpose of extracting the dead wasps, and also as many of the live maggots as can be got at with a long pair of forceps. This opening also serves to expose the internal arrangement of the cells. It is interesting to preserve the entrance-hole entire. I believe there was not one person in this village who was at all acquainted with the actual appearance which an entire wasps' nest presents, until I exhibited some which I had prepared. They had blown up many with gunpowder, and had dug them out in a confused mass, and were not even aware that they had an outer coat, as the wasps hollow out the large cavity in the ground, from the roof of which they suspend the nest, by carrying out the earth in small particles, and the stones continue subsiding to the bottom, and may always be found forming a rude pavement below. Some large stones are sometimes so gradually exposed whilst the nest is increased, that I have found them completely embedded in the midst of the comb. Indeed, there are many little interesting particulars connected with the economy of wasps which I have noticed since I came to reside in the country; and if those of your correspondents and readers who take delight in contemplating the works of Nature, will be at a little pains in examining and preserving some of the wasps' nests they wish to have destroyed, they will not find their labour lost. I will mention, for the sake of

---

* A Descriptive Account of an Improved Method of Planting and Managing the Roots of Grape-Vines. By Clement Hoare, 12mo, Longmans, 1844.



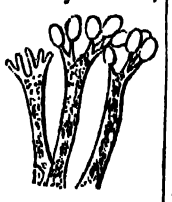
* A kilogramme is rather more than 2 lbs. 3 oz. The substance may of course be made on a small scale, with 20 lbs. of sulphate of iron, 2½ lbs. of sulphate of zinc, 1 lb. of charcoal, 26½ lbs. of plaster of Paris.

persons unacquainted with entomology, that we have four species of wasps in England; two of these build their nests above ground, and two under ground. Of those that build above ground, the hornet (Vespa crabro) makes use of materials collected from rotten wood, and the other (Vespa britannica) from sound wood; and the same distinction in the materials is also observed in the nests of the two underground builders. The common wasp (V. vulgaris) uses the fibre of sound wood, whilst the anchor-faced wasp (V. rufa) collects only from rotten wood, like the hornet. The two underground species appear to be equally common in this neighbourhood. Beautiful figures of Vespa rufa are given in Mr. Curtis's "British Entomology." The materials of which the comb is made so closely resemble paper, that I have a specimen where the wasps had worked up a piece of blue paper to serve their purpose; and I think it very possible that they may not unfrequently avail themselves of similar substances, though we should hardly detect the source from whence they had obtained their materials, if it did not happen to be so highly coloured as in the instance I have noticed. How marvellous it is that a single queen should have been ascertained to lay as many as 20,000 eggs! I have found as many as 500 young queens in a large nest. I once brought home in a bandbox a hornet's nest, which I took out of the roof of a cottage, after destroying all the neuters, partly by turpentine and partly by catching them with a forceps. Upon placing the nest under a large bell-glass, with a little spirits of turpentine, out came about 150 hornets, half of them drones, and the rest young queens. It was rather lucky there were no neuters left, or I might have been more severely stung than would have been agreeable; the queens were too sluggish to attack me.—*J. S. Henslow, Hitcham.*

DISEASES OF PLANTS.—No. III.

[Fungi.]

Before we enter more particularly upon the subject of the diseases of plants, as produced by Fungi, it will be right to say a few words respecting the parasites themselves. *They are divided into two great classes, distinguished by the structure of their parts of fructification.* In the one, (figs. 1 and 2) the reproductive bodies are produced externally, and very frequently in definite numbers, as two or four, at the extremity of certain privileged cells or threads, which arise from the common mass of cells, forming a more or less compact tuft or disc, or built up into variously-shaped processes, as gills, tubes, &c., which distinguish the several genera; or, in the second case, (fig. 3) within the cavity of certain cells distinguished generally, as in the former case, from the other constituent cells, and most frequently eight in number, disposed in one or two rows.



1. — *Agaricus elixus*, (Sow.) Sporophore, with its four long sterigmata and small spores.
2. — *Agaricus semiovatus*, (Sow.) Sporophores, with their four sterigmata, and spores in various degrees of development.
3.—Helvella elastica; asci, and sporidia.
4.—Sporidium of Tuber magnatum (Piedmontese truffle), with its ascus, from a sketch sent by Dr. Montagne.
5.—Sporidium of Peziza aurantia, with its two nuclei.
6.—Single sporidium with its large globose nucleus.

This distinction, however, though apparently so simple, and confessedly of the very greatest importance, is, unfortunately, not always very easy of application. In some cases, from the minuteness and tenderness of the parts of fructification, and the extreme flaccidity of the neighbouring cells, it can only be ascertained by very nice manipulation, and a practised eye; and often, in particular stages of growth, the vegetation is so rapid, that an hour or two will induce such changes as completely to mask the original structure. In other cases, the two modes of structure approach each other by such nice gradations, that it is not always easy to determine with precision to which particular type a particular form of fructification ought to be referred. In the latter case, however, as in that of analogous difficulties amongst phænogamous plants, the question frequently is solved by watching the progress of germination.

Such difficulties, however, attend the naturalist in every branch of science; the most important characters are often those which are most difficult of access; but, as in the study of phænogamous plants, it is not necessary for every ordinary lover of plants to enter into all the minutiæ of structure which engage the attention of the physiologist, though all satisfactory arrangement of organised beings depends upon such points being rightly ascertained and understood. So in the study of Fungi, a little experience and tact will enable a person, without much difficulty, to refer a species to its proper place in the system.

To the first division, then, belong the greater part of those Fungi which are most attractive from their size and qualities, such as the large tribe of Mushrooms and Toadstools, together with the species, often of a leathery or corky texture, which grow on timber, producing the various forms of dry-rot, and supplying the amadou of commerce. The greater part of these have the hymenium perforated with thousands of pores, by means of which the fructifying surface is multiplied; but not a few have the sporiferous disc perfectly even, or at least only indistinctly or irregularly rugose. To the same group belongs the Puff-ball Tribe, whose structure, however, in consequence of the early stage of growth at which it is entirely effaced, has only very lately been ascertained; as is the case also with the tribe of Phalli, of which one species is well known, even to superficial observers, from its disgusting odour. A portion also of the underground Fungi has been shown by Vittadini, Klotzsch, Tulasne, and others, to possess a similar structure. And still more lately the pretty little cups like birds'-nests, which are never seen without attracting admiration, have been shown most unexpectedly, by those admirable botanists, the Messrs. Tulasne, to belong to the division in which the spores are produced externally on certain cells of the hymenium. In a portion of the Puff-ball tribe, however, which in a young state are creamy or mucilaginous, amongst which is reckoned the frothy yellow Fungus so common in hothouses, and so annoying from the dirt produced by its multitudes of sooty spores, the structure has at present not been ascertained precisely, though there is great reason to believe that they will be found to resemble, in this respect, the more known form of Puff-balls, with which they have been so long associated. After these may be reckoned the Fungi which grow on the green parts of living plants, penetrating their tissues and preying on them, which will occupy much of our attention under the various heads of Mildew, Blight, &c. To these may be added a number of minute species of various characters, which, though interesting to the systematist, are mostly of little importance as regards our present object. And lastly, a large portion of the moulds, properly so called, which are often active agents of destruction, and, as will be seen by the annexed sketch of Botrytis curta, perfectly resemble the elements of which the larger and more perfect Fungi are composed.—*M. J. Berkeley.*

APPLE ORCHARDS IN DEVONSHIRE.

A few years since, after a long and tedious ride from London, on the outside of a coach, during a drizzling damp day and night in autumn, I found myself comfortably settled down in Devonshire. I was much delighted with the large extent of Apple orchards: some were loaded with large quantities of pretty tempting cherry-cheeked fruit, and of others the fruit was collected into heaps, perfuming the air with such a mouth-watering fragrance that on the first opportunity I was naturally led to gratify my wishes by tasting such pretty-looking objects. I soon discovered, however, that they were not so good as they looked to be, but were grown for the purpose of being ground down for cider, which is certainly a very good and pleasant beverage when well made. In making it I find that good fruit, good, clean, sound casks, and strict attention to continually racking it when showing the least symptoms of being moved or fermented, are the principal and grand secrets for securing, in good condition, this favourite beverage.

Perhaps now, after residing in this cider-county, amongst the Apple orchards for some years, it may not be uninteresting to give some account of the method of cultivation followed in such orchards here. The trees are planted, to a large extent, apparently without considering what sort of soil or situation is best, and without making any previous preparation; a situation is chosen, a pit is dug with a curious clumsy bit of iron, having a large socket-hole at one end of it, in which is driven a long strong pole, which answers for a handle; it is worked with both hands over one knee; the depth that the roots are buried does not seem to be of any moment, provided the trees are firmly fixed, so as to prevent the wind from driving them down. I have never observed any pruning performed, except such as is done by bullocks, horses, donkeys, &c.; and as I have never observed any "horse-ladders" here in use, of course the pruning is not very effectively performed about the top part of the very lofty trees. The only digging or stirring the surface of the ground among the trees that I have observed is done by pigs, which are occasionally allowed to rove in some orchards at certain seasons of the year, with the rings taken from their snouts. In a moist season these intelligent animals occasionally turn up the ground in a tolerably regular manner; and where this is the case the good effects of their industry are obvious! However, it is only on rare occasions that they are allowed to perform this surface operation. The animals that do the pruning are the principal business-performing creatures, as, in addition to that operation, they tread down the under crop of Grass, weeds, and other rubbish, take the fruit to the cider-mill, and the cider to the consumer; besides, on rare occurrences, a little manure is conveyed by them and placed over the roots, close to the trunks of the trees; it is sometimes, although rarely, placed at the great distance of three or four feet from the trunk. Bipeds, notwithstanding, perform some of the most interesting and essential parts, such as planting, collecting the fruit, consuming it in part, and assisting in making the cider; together with shooting at the trees annually on old Twelfth Night. Let it rain, hail, blow, or snow, this very essential and interesting ceremony is always commenced at 12 o'clock at night, a tremendous fire being kept up for several hours afterwards. They repeat or sing the following interesting song, with all the might which their lungs will permit. The juice of the fruit is generally made use of for many hours, pretty freely, previously to this interesting ceremony, so that a perfect ripeness of address and expertness in gunnery is the result. Guns and fire-locks long laid by are on this remarkable occasion brought forward. The following is what I have heard sung on these occasions, although much more is added in some localities:—

"Here's to thee, old Apple tree,
Whence thou mayest bud, and whence thou mayest blow;
And whence thou mayest bear Apples enow;
Hats-full! caps-full!
Bushel—bushel—sacks full!
And my pockets full too!
If thee does not bear either Apples or Corn,
We'll down with thy top, and up with a horn."

[*Here the natives shoot at the trees.*

Not being acquainted with the custom here on the first old Twelfth Night, I must acknowledge that I was somewhat alarmed at such a continual loud and rattling report of fire-arms in every direction, living as I did in a rather retired spot, away from any other residence. It was a cold, gloomy, dark, and still night, and being suddenly awoke by the loud reports of fire-arms, I could not guess the meaning of it at that untimely hour; I imagined at first that it was an affray with gamekeepers and poachers, or with smugglers and blockade-men; and, suddenly hearing a shrill vacant kind of hallo in a plantation close by, I fancied at first that it was some poor fellow who had been wounded in the affray: on getting up, however, I found that it was a couple of owls answering each other; they were as happy as could be, and the firing, I soon found, was in no particular spot, but went pop, bang, east and west, north and south. On making an early inquiry next morning, I was informed that it was the yearly custom.

The Apple trees, with few exceptions, are entirely left to nature, consequently they are entirely covered from top to bottom with long Moss and Lichens; the wood and branches are as thick as those of a weeping Willow; the fruit is generally very small and corey. The varieties are not numerous: they seem all in this locality to cultivate the same kinds. I have sometimes thought other good sorts could be beneficially cultivated—some of the large, free-bearing, juicy varieties, such as the Hawthornden, Keswick Codling, Kentish Beauty, Kentish Fill-basket, &c. When I make mention of those sorts, and a number of others, I am always informed that they will not answer hereabouts, although I have never met with one person that had ever attempted, or that had ever heard of any one else attempting to introduce them! I should be rather inclined to think that those large juicy kinds, cultivated for mixing with the little Bitter-sweets, would not be amiss, although I dare say, under the present system of cultivation, they would not be produced very large or juicy. The leaves of the trees show great poverty; they are small, thin, and are not much larger than Damson leaves; they turn yellow, and fall off in some localities long before the fruit has arrived at perfection; and the abundance of long Moss and Lichen in my opinion to a certain extent indicates poverty.

I will here attempt to describe three different orchards, under the management of three different persons. The first is an orchard of above 12 acres in size; the owner never digs, manures, or prunes himself, but leaves those operations to be performed by his cattle; he does not allow pigs to run in his orchard, therefore he has no digging done; and the consequence is, that he does not get a tree to bear fruit once in seven years. He lately informed me that he should not have Apples enough this autumn to make four hogsheads of cider; that the seasons were now so unfavourable he could get no Apples; and were it not for the grazing for his cattle underneath the trees, he should have no return, which was now become a very poor one. I asked him why he did not manure the trees; in reply, he observed, they have all that the cattle make among them; we do not mow, or carry anything away from them. The second is a small orchard about one acre in extent, the owner of which manures about his trees every season; here, however, there is no digging done. The trees are healthy, they grow and make wood, and produce large thick dark-green leaves and strong buds; they are not so thickly covered with Moss and Lichen, and rarely fail to bring forth a heavy crop of good fruit. This person's cider is much sought after, being good, and of course of more value. He makes a larger quantity of cider than the person mentioned above, with his 12 acres. The last is a small orchard held by another individual, who keeps no other cattle besides pigs, which are allowed to rove at freedom about the orchard; and as the rings are taken out of their snouts in autumn, when the ground is nicely softened by the rains, and the worms are working near the surface, those worthy animals rout and turn up the surface in a tolerably regular way. From the digging and manuring by the pigs, and from what the holder can muster, this is the best bearing, healthy, orchard in the district. It produces the best cider and the least Moss and Lichen. This shows how beneficial a little surface-stirring with the addition of a little manure is. A considerable quantity of cider made and consumed hereabouts is very poor, the visages of the men who are in the constant habit of drinking it are sallow and wrinkled. Only fancy drinking daily, old cider sour as vinegar!—*Zur.*

Home Correspondence.

Horticultural Society of London.—I see by the list of prizes offered by this Society for next year, as advertised lately in the *Chronicle*, that although the prizes given for some classes of plants have been justly raised in value, no addition has been made to the prizes offered in the Fruit-growers' class, at which, considering the competition that has taken place of late, and the great interest felt on the subject by all the growers of fruit, I have conversed with on the subject, I am much surprised. It appears that the Horticultural Society are placing the practical forcing gardeners in a lower class than that of the plant-growers. I hope that exhibitors of fruit at the Chiswick Shows will not rest satisfied until their exertions are as handsomely rewarded as those of the growers of stove and greenhouse plants. I shall say no more at present, but hope my brother-exhibitors will endeavour to persuade the Council of the Horticultural Society to place them on the same footing as the two other classes for which the large gold medal is awarded.—*An Exhibitor of Fruit at Chiswick.* [The best answer to this letter is, that *there was not one single letter sent by a fruit-grower* to the Vice-Secretary for the consideration of the Committee; the conclusion from which was, that the fruit-growers were satisfied.]

Gathering of Fruit.—The proper time for gathering fruit differs with almost every variety; but, generally speaking, there are only two periods for gathering, viz., summer and winter—the former for such kinds as drop from the trees between midsummer and the middle of October, and the latter for such sorts as hang upon the trees until frost brings them down. The proper time for gathering the first sorts is indicated by their colour, or more certainly by their beginning to fall; when you see a few down go to work, and, looking over the tree, pick off all the ripest, which always come down first, leaving the others on the tree until they in their turn show symptoms of being easily detached from the bough when slightly grasped by the hand; or, as before, take them when they begin to tumble to the ground. The next operation is to lay them out carefully, one by one—not placing them one upon another—in some place that is fully exposed to the sun's rays during the whole day. In a week you will see a wonderful alteration in the appearance of them, and in three weeks they will be in a fit state for storing. By this method they acquire a very superior flavour and appearance. The advantage of exposing them to the sun is, that every individual Apple sweats itself dry, which renders it fit for keeping for a length of time. Early on the second or third morning of exposure, they will be found to be bathed in sweat, and thus their acid qualities are expelled and their saccharine matter is concentrated. Of second or late sorts which show no symptoms of ripening on the tree, of course they cannot have the same advantage of the sun's rays as the summer varieties; when frost is expected they should be gathered, and, if possible, exposed in Melon-pits or frames in which air circulates freely; they should be treated as nearly like the others as the season will admit. The next thing to be considered is the storing of them, and this is of some importance. How creditable it is to have a good Ribston Pippin, for example, fit for table in April or May, instead of its being unfit for use in January, as is generally the case! My Apple-room was at one time fitted all round with racks; the bars of wood were two inches thick, with a space of one inch between them. The Apples were laid singly upon a layer of Wheat-straw, but I found that this did not answer; for when the door and window were shut, the fruit became covered with mould and damp; and if I gave air, they were sure to shrivel. I could find no medium between these evils until I had my room fitted upon its present plan. It has a northern aspect, and is covered with a good thickness of thatch. This answers better than slates, as it keeps the cold and frost out in winter, and also the heats in summer. Inside I have it fitted up all round with drawers 8 inches deep, 2 feet wide, and 2 feet long. They are made to fit tightly. Each drawer has the name of the fruit which it contains labelled on the outside. These drawers are half-filled with fine paper-shavings, and the fruit is carefully packed therein; or, in the absence of paper-shavings, I find clean Oat-chaff to answer equally well, each fruit being first wrapped in silk papes. By this method I can have good fruit during the greater part of the year.—*James Wilson.*

Water Wagtail.—The reading the remarks on the Water Wagtail last year, p. 392, revived in my memory a circumstance which occurred in my youth, that I shall probably never forget. The subject being again lately introduced, induces me now to offer the anecdote:—In the autumn of 1830, we had the house full of company. Being the eldest son, and occupying one of the best bedrooms, I was requested to turn out; I did so, and slept in a room in the roof. Some of my young friends were arranging an early start the following morning to shoot rabbits. With the bed-candle in my hand, on the point of retiring, I volunteered to join the party. I was laughed at and told they should be back again before I was up. I offered to bet them a shilling each I would be the first up. It was readily taken. About 5 o'clock I was awoke by a dactyl rap. I started, and thought it was quite up with my shillings, when I heard it repeated; and presently I perceived it was done by a Wagtail at the window. I felt somewhat easier for the fate of my shillings, which feeling was not decreased on opening the door, and hearing nothing but most sonorous sounds all through the gallery. I soon roused my friends, whom I rejoiced to find performing similar notes to the company's servants above. It was now my turn to laugh. The elegant little creature performed this kind office just before sunrise every morning during the fortnight I occupied the room. I generally took its gentle hint, astonished all the family, and almost established a character for early rising. Opening the window seemed to disappoint my little friend and put very much, which led me to suppose he came purposely to admire himself in the glass. Your correspondent says, in his case this could not have been so, as there was no blind to the window; nor was there always in my case. Neither do I think a blind absolutely necessary to produce reflection; the interior of a house being darker than the exterior, the window-glass will generally reflect exterior objects as well, or even more perfectly, without it. I have inquired, but cannot learn that the bird visits any other window in the house. Servants, unless superstitious, seldom regard such a matter. My housekeeper, who has occupied this room for the last five years, says every year during the summer she is frequently awoke by a bird tapping at the window. It had not occurred for a month or more. She does not exactly know what bird it is, but thinks it is the Dishwasher, which I imagine must be the Water Wagtail, though probably not the same kind as your correspondent's "Boarula;" for his friend, I observe, visits him only during winter, whereas we have the yellow and another here all the year round. The former is larger, and I think a rather more graceful bird.—*B. Chilo., North Devon.*

Dog Rose.—Does the old name of Canker, or Canker-rose remain in use amongst the vulgar (the most enduring repositories of the vernacular), in any part of the kingdom? It must have been in familiar use in Shakspeare's day:—

D. John. I had rather be a Canker in a hedge, than a Rose in his grace.—*Much ado about Nothing.*

Hot. To put down Richard, that sweet lovely Rose,
And to plant this thorn, this Canker Bolingbroke.—*K. Hen. IV.*

And yet it is curious that Gerard does not mention it in his account of the plant; although it is, I suppose, erroneously introduced into his Index, thus—"Canker-rose, *i. e.* Poppy," for it is not to be found in his "History of the Poppy and his kinds." Gerard did not live in the country, properly speaking, and dealt more with Dioscorides and Theophrastus, Mathiolus and Lobelius, than with the wits of his time, and therefore probably never met with the country name of Canker. I am puzzled to know why it was called the Canker-rose. The commentators on Shakspeare quote a contemporaneous authority or two in illustration of the use of the word, but afford no other light on the subject. Johnson goes no farther than the definition. Booth, to whose "Analytical Dictionary," (1835), I often refer with great satisfaction, under the head Dog-rose, says it was called Canker-rose because of its hairy galls. This is not very satisfactory, and does not carry us near enough, I suspect, to the original appropriation of the term. Is there any authority for such a German compound as kanker-gallen, or gallapfelen—spider-gall? and has it been applied to the excrescence in question? If so, then one's mind is led to think of a Gothic or Celtic original for canker, cancer, *κάγχρος*, sea and land spiders, and other rough things, and such like pleasant etymological reveries.—*P. P.*

Pelargoniums.—I am pleased to see that the beautiful Cape Pelargoniums are likely to come into fashion again. A favourite plant with me is P. echinatum. A few cuttings, struck at three times in the year, will keep up a succession actually all the year round. It strikes very freely under almost any circumstances, while in a growing state, and thrives in loam, peat, and white sand. My large plant has now fourteen trusses, and looks like a cloud of white butterflies with pink spots on their wings.—*Micklewell.*

Hints to Botanical Collectors.—Much unnecessary anxiety might be spared those to whose care newly introduced plants and seeds are consigned, if collectors would attach some memoranda to them, not only concerning the soil in which the plants delight, with some cursory remarks on their habit, which is, in many cases, all the directions given by which the cultivator is to be guided in their treatment, but also the climate, the degree of temperature at various periods of the year if possible, and above all, the situation in which they grow. When I speak of collectors, I do not refer to persons whose sole object in exploring distant regions, is collecting not only the productions of various climes, but also giving an account of their habits, &c.; I allude to persons who, by some cause either of business or pleasure, are induced to visit distant climes, and being for the most part entirely ignorant of botany and gardening, and, consequently, their knowledge of plants in general being limited, collect indiscriminately everything which comes in their way, thinking, because they had never previously seen them, they must be unknown in this country. In this way a host of rubbish is constantly being introduced, to be a trouble and anxiety for, perhaps, two or three years, and then to be cast away. But supposing that there should be one plant out of the many worthy of cultivation, how are we to be guided as to its treatment? Many a beautiful plant has undoubtedly died in its infancy solely from a want of proper treatment, arising from the above causes. The only guide which those collectors deign to give, is something after this manner:—"A beautiful blue flower from New Holland;" "Liliaceous plant;" "A shrub resembling a Symphoria;" and such-like vague descriptions, from which nothing of any importance relative to the proper treatment of the plant can be gathered. A plant may be a native of a very warm country, and yet, growing on elevated situations, would require a temperature very opposite to what would be supposed from the mere knowledge of its coming from such and such a country. Suppose two plants were brought from Mexico, one from the plains, the other from a mountain several thousand feet above the level of the sea, and the only guide to their cultivation given was, that they were natives of Mexico—the consequence would be, both would be subjected to the same treatment—probably a hot one; in which, while one may luxuriate, the other—it may be the more valuable specimen—would perish. In a word, gardeners in general should study the physical as well as geographical situation of plants, as a means of rendering their labours more easy, and as pointing out a shorter way to the attainment of the desired end, viz. successful cultivation.—*Walter Wakefield.*

Flower Gardens.—Will some of your correspondents point out the best method of ornamenting the flower-garden at this time of the year, with those beautiful plants, the improved varieties of the Pelargonium? I have one now in the open border, which was very hardly treated during the winter, and did not bloom in spring, which is blossoming as well as if it were in Mr. Catleugh's greenhouse. They will probably not last as long in blossom as the scarlets, but they would be very beautiful for a considerable time. They seem, like the Fuchsia, to grow and blossom, and blossom and grow. I think they might possibly be made the most beautiful of all border flowers, by a little delaying management. Why should all gardeners attend so exclusively to spring flowers, and so totally neglect the autumnal? I am very much inclined to think it is because of the London market; but they should recollect that the same affluent people who live in London in the spring, live in the country in autumn, and are as vain of their gardens as peacocks of their tails, if they happen to have them in tolerably showy order.—*Autumnus.*

Monstrosities.—Why do Vines, Fuchsias, &c., put out roots frequently at their joints? Even Pelargoniums, in small pots and a feeding atmosphere do this, as do also Melons and Cucumbers, even with full scope for their roots. Potatoes show the same inclination; and the stem in some instances thickens, which growth certainly arises from the tuber not having a sufficient supply of moisture to induce it to throw out roots to increase its kind in the way natural to it; and, taking advantage of all its leaves can collect, and the parent tuber supply, what would be leaves and young side-shoots are converted into tubers. The should-be-eyes for the same purpose throw out small leaves, no stems, and again Potatoes (green Potatoes) instead of green leaves and stems are produced. Of this I had a beautiful exemplification last year on my Pansy border; the ground the previous year had been planted with Potatoes, (the Early American and Blue Laurel); some of these being left in the soil grew. The ground had been double-dug, in order to prepare it for the flowers, and the tubers were cast too deep to be got up without injury to several plants; the spot where they grew became the regular path, trodden and baked hard. The stems grew, as I have stated, and were borne down by the weight of tubers, which increased rapidly; I laid weeds, a few at a time, upon some of them; they thus lost a little of their deep green appearance. I then put a compost consisting chiefly of decayed leaves over the weeds, slightly earthing them; after a time some of these tubers protruded, that part acquiring the colour of all exposed Potatoes, that covered being white; the eyes of one part sunk, while the green had the vegetating appearance of the uncovered ones on the stems. The part I tried this upon was the middle of the stem, and I covered rather more than ½ of it. The stem retained its verdure much longer than the others, but from lying on the ground many of the tuberous excrescences were entirely eaten by snails. One plant that was dug for, had not one Potatoe at the root; the others were covered with straw and earth, and were to remain till spring; they were, however, lost or thrown away, I was anxious to see what they would do when cultivated this year.—*A. W.*

Wasps.—I am sorry to learn from "H. P." that he has not succeeded in destroying a wasp's nest by means of spirits of turpentine. It must be borne in mind that the nest of wasps is seldom perpendicularly under the entrance; the instinct of the animal, no doubt, directs a different arrangement, as a security against wet. I have found that after the wasps enter the hole, they proceed for a few inches in a line almost horizontal, and then take a more perpendicular route to the nest, which will be at some distance from the entrance. The bottle containing the spirits of turpentine is here of great value, because you can insert the neck in the direction of the horizontal passage, and then the turpentine will go direct to the nest; if these conditions are observed, and all air excluded by means of mud or clay round the top, it is impossible that the wasps inside can escape destruction. Although a small quantity of turpentine may be sufficient, yet as it is a cheap article I would recommend about a quarter of a pint for each operation.—*Jasper Stokes, Birmingham.*——Another correspondent, signing himself "A. K." says, "I tried the experiment of destroying wasps' nests by turpentine in a bottle, on two nests; in one which was not deep in the ground it completely succeeded; in the other, which was much deeper, it failed. My gardener then poured hot Stockholm tar into the hole, and this answered perfectly; all the wasps were destroyed. He has since destroyed another in the same way."——*Rougham* remarks that "an easy, cheap, and effectual way of destroying a wasp's nest and the swarm is to pour a pint of gas-tar into the hole, or if the hole is large and placed inconveniently for pouring, stuff into it a wisp of straw dipped in gas-tar. No wasp can rush out to attack you, and every wasp which may be abroad will be caught and disabled on his return home."——*Did*

"H. D." who complains that turpentine had not killed his wasps, (*ante* p. 621,) stop up both holes? as wasps have generally two entrances to their nest, and without both are closed the fumes of the turpentine could not of course act. I can speak to its complete success if properly attended to.—*D.*

Strawberries.—Respecting the cutting off the leaves of Strawberries, I beg to mention that in a border containing 45 beds of the following kinds, viz., Keen's Seedling, Downton, Roseberry, Wilmot's Superb, Pine, Hautboy, Myatt's Pine, Elton Seedling, Carolina, and Knevet's Seedling, after the fruit was gathered last autumn, I mowed the leaves off every second bed, and raked them off lightly, making straight the sides of the beds, and hoeing the alleys; I then threw the soil over the beds that had been loosened with the hoe; the other beds had nothing done to them except weeding when it was necessary. During this season there was no difference between the crop on the beds that had not been touched, and that on those which had had the leaves mowed off. I have had the management of Strawberries for nearly 60 years, and I have for the most part grown them in 4-feet beds, and, except near walks, I have treated them as above, and I have always fine crops of excellent fruit. As to manure, I never thought of it, except for Myatt's Pine; I always found my plants to grow quite strong enough, and even rather more so than I could have wished. On Strawberries grown in beds the fruit is always clean, which is not the case with that on single rows; besides, the small quantity of soil spread over the plants from the alleys, supports and strengthens them, as well as assists the young runners in striking root. I have always found the produce of the third year after planting the best. I am sure that the bed system of culture is the most suitable in every respect for market-gardeners: the produce is nearly double that of single-row culture. I have read the remarks at p. 555, 1843, which I consider excellent; but as I have always obtained good crops from my old method, I still continue to practise it.—*J. H.*

Cats and Valerian.—With regard to Valerian and cats, a correspondent signing himself "Autumnus," by way of suggestion, writes:—"Might not gamekeepers use bundles of Valerian to catch wild cats in the cover? Might not the owners of barns, outhouses, ships, and other places infested with rats, use the Valerian to assemble their enemies, and our friends the cats?"

Scorching Effects of the Sun.—In the *Chronicle* I have read, with some surprise, statements which I have thought resulted from want of observation, upon the spot on Vine leaves, &c. Nothing coincided with my practical observation except the paragraph by "Vidimus," p. 540, which I see, unfortunately for my own opinion, you do not encourage. You say, How do the lenses get into focus? Another question appears to me to answer this—Do not the drops of water shift and change their form, and run down the glass before they can act? It is not while the glass is covered with steam sufficient to form streams, and constant and frequent droppings of water, that the injury is done, for the course of these drops is devious; a larger drop of steam being added to the current, one hastens as well as directs it progress, and the leaves upon which these drops fall being still moist, the additional moisture readily spreads over a larger surface than it would do if they were dry, and a general evaporation and absorption takes place; the glass also dries by degrees; but large drops of water will hang upon it for a long time after the sun has dried the surrounding surface; these tremble, oscillate, sparkle like brilliant suns, sometimes drop, sometimes run, and, meeting at the next fold of the glass a little more moisture, or on the flat pane a dew-drop, there stop, either to oscillate into the focus to form a burning-glass under which the foliage suffers, or, the addition being too great, it runs forward and drops, or is evaporated at a fold, or stands till it can get through, performing its work of destruction. My observations were made upon a Melon-pit, 17 feet by 7 feet wide: and, as I was the sole worker of it, the spots and mildew or fungus proved an annoyance; and when I searched gardening books I was no wiser. Gardeners said, with great composure, "We all have the same complaint; there is no remedy but pulling off the spotted leaves; it may be a flaw in the glass, &c.;" and I was no better off, but resolved to have some idea of the truth. My pit was constructed with a flagged footway at the back, from which the centre could be reached; this I mounted to make my observations, and the result was as above. Then for the remedy. My frames were made so that I could let air or steam out at the upper part, without admitting a thorough draft by the entrance of air at the bottom; and by thus permitting my glasses to dry, I secured the plants from spot. In very hot weather I watered from 8 to 9 o'clock, A.M., and also while the sun was on the frame in the afternoon, and shut up early; when my fruit was setting and swelling, at 5 or 6 o'clock; and 4 in cloudy weather. I never failed having abundant crops of high-flavoured well-grown fruit. With the Persian Melon in pots in the same pit I was equally successful, neither spot nor spider showing themselves. In the same frame I have grown the Manchester Green Spine Cucumber 26 inches long, and had six, seven, and eight to cut at once of this size while my Melons were setting and growing; but when the Cucumber Vines began to interfere with the Melons, I cut them up or cut them to one stem, and trained it along the bottom of the pit below where the Melons run. I worked my frames with what gardeners called a scalding heat, but I never had a twig hurt by it, and my pit was never filled till April, yet I could generally obtain two crops of fruit off the same roots.—*A. W.*

Destroying Worms.—In the Calendar of Operations of the 7th, "*D. B.*" directs gardeners to look over all their plants in pots, in order to see if the drainage is right, and that there are no worms in them. This is attended with some disadvantage, especially if the plants have had large shifts, and have not had time to fill the pots with roots. Let persons be ever so careful in turning a plant out of the pot, they are sure to disengage the drainage. I have been much annoyed by worms getting into my cutting pots, and on turning over a compost heap, on which I had put a small quantity of gas-water, and finding that there was scarcely a worm to be seen, I took four gallons of gas-water and poured it over the bottom of a three-light box, which I was about to use for cuttings; over this I spread about four inches of sifted cinders, and the result has been equal to my expectations; not a worm has dared to come through as yet. The gas-water covered over to that depth has not affected the cuttings, neither is there the least disagreeable smell from it. On no account, however, use gas-water in any house, pit, or frame, without covering it over with some kind of material, or it is sure to destroy your plants. When I fill my tan-beds, I intend putting a quantity of gas-water all over the bark, about a foot below the surface, and also below all plants standing out of doors.—*A. Threlkeld, Headingly House.*

Bees.—As the questions put by "A Lover of Truth" (p. 572) appear to me not to be satisfactorily answered, I beg leave to say a few words on the subject. Dr. Bevan and others say that a queen-bee lays three sorts of eggs, and that she knows what sort of eggs she is going to lay. It is even stated that queens commence to lay drone-eggs at certain seasons of the year, and that the great laying takes place about the beginning of May. Last year I hinted that a queen lays only one sort of eggs, and this I still affirm. In March or April take a strong and a weak stock, containing equal quantities of drone-comb, occupying the same place in each hive; the strong one will commence to breed drones about four weeks sooner than the other. Exchanging the queens will make no difference. If one hive contain double the number of drone-cells, double the number of drones will be bred in it, even though the queens are exchanged. If we were to place a bit of drone-comb in the centre of the weak stock, where brood is just hatched, it would breed drones before the strong one. "A Lover of Truth" will now, I think, naturally and justly conclude that the season of drone-breeding, and the number of drones bred, do not depend on the laying or eggs of the queen, but on the situation and number of drone-cells in the hive, and that if the comb which he speaks of had consisted solely of worker-cells, there would perhaps not have been a single drone hatched in it. It would, however, be uncandid not to acknowledge that a pretty weighty objection can be brought against this assertion, viz., that the queen-bee lays only one sort of egg; but I imagine that this will not overturn it, and that those who dispute this point will find it difficult to maintain their assertions by fact and argument.—*A. Pettigrew.*

Cape Iridaceæ.—I have flowered a few of these for several years with uniform success. My simple means and directions are as follow:—Listen to no printed and reprinted stories about cold frames and south borders. The cold frame plan is uncertain at best; and as to the south borders, look at your Ixias after a thunder shower. The place for the delicate and lovely little things is the greenhouse, where their frail beauty will bloom unruffled, and will be, as it invariably is, the attraction of all eyes on entering the house. Purchase selected roots from a respectable seedsman every year; get them as soon in the season as you can, and pot them immediately in any of the prescribed composts, provided it be turfy, sandy, and peaty, and mixed with cow-dung.—*Micklewell.*

Sulphate of Iron.—Your Leading Article of some two or three weeks since, on this subject, has misled some men who pin their faith on your judgment. You stated it could not cost more than 4*l.* 4*s.*, but I find from my invoice that a ton costs 5*l.* 11*s.*; and one of the first manure merchants in London writes—"I am of opinion its general application or its cheapness cannot be put in competition with sulphuric acid."—*Suffolk.* [We repeat that sulphate of iron can be had of Mr. W. Northcott, 13, Rood-lane, Fenchurch-street, at from 3*l.* 15*s.* to 4*l.* 4*s.* a ton, according to the quantity taken. It is much more convenient to employ than sulphuric acid, as well as more useful; because it decomposes sulphuretted hydrogen, and removes bad smells, which sulphuric acid will not do.]

Societies.

ROYAL SOUTH LONDON FLORICULTURAL SOCIETY.

Sept. 17.—This Exhibition, the last for the season, was held in the Surrey Zoological Gardens. The display of Dahlias, which always form the principal feature of the September Meeting, was not upon so extensive a scale as on former occasions. The Chelmsford Show having been appointed for the same day kept some of the usual exhibitors away; but the general appearance of the stands was good, and several of them excellent. The Silver Cup, value 5*l.* 5*s.* presented by the Committee, for the best 24 Dahlias, was awarded to Mr. Cook for Princess Royal, Perpetual Grand, Phenomenon, Prince of Wales, Mrs. Shelley, Model of Perfection, Widnall's Queen, Admiral Stopford, Competitor, Essex Triumph, Burnham Hero, Nonpareil, Standard of Perfection, Queen of Trumps, Victory of Sussex, Indispensable, Crimson Perfection, Beauty of Sussex, Hero of Stonehenge, Blue Bonnet, Lady Antrobus, Pet Rival, Favourite, and President of West.—Among *Amateurs* the 1st Prize was awarded to Lady Paget, Chelsea Hospital, for Burnham Hero, Widnall's Queen, Princess Royal, Sir Robert Sale, Mrs. Shelley, Admiral Stopford, Antagonist, Aurantia, Hodge's Competitor, and Dodd's Prince of Wales—Mr. Bushell, of Kennington, obtained a small Silver Medal for the following, viz., Emma, Hampstead Rival, Admiral Stopford, Widnall's Queen, Victory of Sussex, Lady St. Maur, Pickwick, Mrs. Shelley, Prince of Wales, Essex Triumph, Vivid, Great Mogul, Regina, Bianca, Pet Rival, Hudson's Princess Royal, Applause, Mara, Queen of Trumps, Aurantia, Nonpareil, Uxbridge Magnet, Beauty of Sussex, and Mrs. Hanley.—To other stands no names were attached. Several seedlings were exhibited, but none of first-rate quality. Several blooms of a very fine seedling Pansy, named *Pisarro*, was exhibited by Mr. Thompson, of Iver, to which a first class Certificate was awarded. This is a well-formed flower, of considerable substance, centre clear yellow, with good eye; the top petals are of a deep bronzy purple, with a broad margin of the same colour surrounding the lower petals; the side petals meet well above the eye, where the belting joins, making the shield of the ground colour complete; a rich and fine flower.—A very pretty variety of the Petunia was shown, named *Invincible*, having a light rosy-lilac ground, with dark throat, and a broad margin of rose colour on the margin of the corolla; if constant this will form a very good variety. Miscellaneous collections of plants were deficient. By far the best present was that sent by Mr. Bruce, gr. to B. Miller, Esq., who received a large Silver Medal for well-grown specimens of Achimenes longiflora, a large plant of Crowea saligna, in good health, but scarce of bloom; a neat specimen of Erica rupestris, a dwarf-growing species, having small white flowers, and a pretty dark-green foliage; together with Cliffortiana, covered with a profusion of slender white blossoms, delicately tinged with pink; and cruenta, a very useful autumn-flowering sort. Mr. Bruce also sent several species of Clerodendron, among which was a beautiful specimen of squamatum, having a fine head of scarlet flowers; an excellent plant of Erythrina Crista-galli, having eight stems loaded with bloom; a large Ixora coccinea, Justicia oblongata, and a plant of Pancratium fragrans, well managed, together with some others, in equally good condition.—A Middle Silver Medal was awarded to Mr. Hamp, gr. to J. Thorn, Esq., for a second group, comprising among others a small but healthy specimen of Gardoquia Hookeri; a good Crowea saligna; Achimenes grandiflora in good condition; and Portulaca splendens, producing beautiful purple flowers; together with a pretty plant of Angelonia salicariæfolia, and a specimen of Lilium lancifolium album.—In the Nurserymen's class the best collection was sent by Mr. Jennings, of South Lambeth; it consisted chiefly of Petunias and Fuchsias, among which was Exoniensis in fair condition, along with the different kinds of Achimenes, and some Roses.—Mr. Jennings also contributed a group of Fuchsias; the sorts were Exoniensis, Halley's King John, Eppsii, Epps's Bridgroom, and Kentish Bride; Smith's Paragon, Dalatonii, Stanwelliana, Brockmanii, Gem, Compacta, excelsa, and Iveryana.—The large Silver Medal offered for the best specimen plants of six distinct Genera, was awarded to Mr. Bruce, for a beautiful small plant of Erica Aitoniana, bearing a profusion of pretty white blossoms; Ixora grandiflora; a fine Clerodendron squamatum, and a plant of Pentas carnea in good condition; together with Russelia juncea, and a plant of Siphocampylus betulifolius. Mr. Bruce also showed, as a single specimen, a magnificent plant of Witsenia corymbosa.—G. T. Cox, Esq., of Stockwell, received a Middle Silver Medal, for plants of Angelonia salicariæfolia, Justicia oblongata, Gomphocarpus salicifolius, and a plant of the showy Aphelandra cristata.—Collections of Orchidaceæ were exhibited by Mr. Schroder and Mr. Cox. In Mr. Schroder's group, which was the best, we observed good specimens of Odontoglossum grande, and Stanhopea Wardii, the latter producing a fine spike of flowers; along with Cattleya intermedia, in fair condition. Mr. Cox sent, among others, the showy Cattleya Harrisoniæ, in a creditable state; Cymbidium giganteum, and a plant of Warrea tricolor.—Mr. Groom, of Clapham Rise, produced several small but handsome specimens of Lilium lancifolium rubrum or speciosum, which is one of the most beautiful of our autumn-flowering plants.—The large Silver Medal given by Mr. Groom to amateurs for the best specimen of either variety of Lilium lancifolium, was awarded to Mr. Schroder, for a plant of L. lancifolium album.—Among miscellaneous objects was a collection of well-bloomed Cockscombs, from Mr. Scorer; and another was contributed by Mr. Atterton, who also showed a group of Globe Amaranthus.—Mr. Jennings sent some dwarf Cacti; and Mr. Bridges obtained a middle Silver Medal for the best twelve Asters. The first prize for the best collection of cut flowers among amateurs was awarded to Mr. Davis; among gentlemen's gardeners to Mr. Bruce; and among nurserymen to Mr. Wood. Mr. Parsons obtained a middle Silver Medal for the best twelve bunches of cut Roses; and in the nurserymen's class Mr. Paul was awarded a middle Silver Medal for the same.—Of FRUIT and VEGETABLES some good samples were exhibited. Among gentlemen's gardeners Mr. Kay obtained a middle Silver Medal for the best four sorts of fruit; and Mr. Atterton was awarded the same for vegetables. Among nurserymen Mr. Burdill and Mr. Gaines were first. Mr. Parsons received a middle Silver Medal for good specimens of Black Hamburgh and Muscat of Alexandria Grapes; and fair bunches of Black Hamburgh Grapes were also shown by Mr. Chapman.

BOTANICAL SOCIETY OF LONDON.

Sept. 6.—J. Reynolds, Esq., Treasurer, in the Chair. Mr. T. Ingall presented a specimen of Teucrium Botrys found in a stony field at the back of Box Hill, between Brockham and the upper part of Headley Lane, Surrey, 4th August last.—Read, Dr. Taylor's description of some new Musci and Lichenes, from the Australian Colonies; namely, Dicranum Menziesii, Bryum leptotheciun, Bartramia tenuis, Hypnum excavatum, Usnea scabrida, and Parmelia tubularis, all of Tayl. MSS.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

Sept. 5.—This was the Quarterly Meeting. Collections of fine Carnations, Flaked Bizarres, and Picotees, were produced by Mr. Young and Mr. Thomson, but no competition being announced for this day, no award was made.—Specimens of a seedling Apricot, raised by Mr. J. Thomson, were tried, and found to be saccharine, juicy, and as high-flavoured as the Moorpark from the same wall, and considerably earlier, having been ripe more than a fortnight ago, and being now nearly past.—Various fruits from the Society's garden were also tried; particularly the Washington, Sharpe's Emperor, and Coul Orleans Plums; Moorpark, Breda, and Red Roman Apricots, with the Raisin Grape, which was considered hardy, having ripened its clusters in a cold greenhouse. Several very beautiful specimens of exotic plants, in full flower, from the hothouses in the Society's garden, ornamented the Hall; particularly Stanhopea insignis, and S. insignis speciosa; Miltonia spectabilis, having several flower-stems, and Clerodendron splendens.—The Secretary read a communication from Mr. J. Lothian, gr. to Mr. Campbell, on the use of Sea-weed as a manure. From the garden being situate on the shore of Loch Killis, ample opportunities are afforded for procuring sea-ware, and for trying its effects on various kinds of soil, and for different crops. Mr. Lothian's experience shows that it is best suited for very light or sandy soils, being of no advantage on heavy loams, and on clayey damp soils positively injurious. When trenched into a sandy soil, sea-ware was found to afford capital crops of Potatoes, Peas, Turnips, and Cabbages. The drift-ware (mixed with Sertulariæ, Flustræ, &c.,) when used as a winter covering for Asparagus and Artichoke beds, proved an excellent fertiliser. When sea-weed was dug in during autumn, between the Gooseberry and Raspberry lines, it was found very useful in destroying vermin, and promoting the vigour and fruitfulness of the bushes.—A number of new members were on this occasion added to the Society.

REGENT'S PARK GARDENERS' SOCIETY.

As a proof that Morphology is exciting considerable interest, a public meeting for its discussion has been held during the week, in the room used for the meetings of the Regent's Park Gardeners' Society. A rather protracted discussion took place, and many interesting specimens, illustrative of the subject, were exhibited. The chairman (Mr. Raith) made some remarks on the history of the science, and then read some paragraphs from Dr. Lindley's "Introduction to Botany," in explanation of it.—A person present then moved a resolution, to the effect that nothing had yet appeared in support of the monstrous doctrine, at all reconcileable with reason or common sense.—Mr. C. Moore observed, that a few months since he was prejudiced against it, but that he had since seen reason entirely to change his views, and had brought specimens to the meeting, for the purpose of proving that Morphology indeed rested on proofs. He produced a specimen of the viviparous variety of Aira cæspitosa, the panicle of which, instead of developing blossoms in the ordinary manner, had produced a quantity of buds, and these, on being spread over the surface of damp soil, had become rooted and established plants; in this case, the glumes never having expanded, he conceived the production of plants from the parts which should have perfected seed, as strong and incontrovertible evidence, that flowers and leaves are natural modifications of the same elementary organ. Allium scorodoprasum, with viviparous heads, was also produced. He strongly advised the dismissal of prejudice in considering such a subject, and a close examination of facts before a conclusion was arrived at.—The person above alluded to spoke in opposition, and endeavoured to explain the cause of plants becoming viviparous, by assuming that the internal parts of the flowers had been enabled to perform their functions, and produce seed, although they had not been visibly expanded; and that this seed had germinated whilst attached to the stem, and thus produced the young plants (!) With reference to the branches produced from the centre of some flowers, he contended that this was a monstrosity similar to what sometimes happens in the animal kingdom, such as a child born with two thumbs, or a lamb with two heads or tails (!) He denied that any of the parts of a plant or flower were not essential, having each a peculiar and allotted function to perform; and contended that God had made nothing in vain, but had formed all things perfect, and that nothing could border more strongly on atheism than this most dangerous and pernicious doctrine.—Mr. Maher, who had before him some beautiful morphological specimens, followed in vindication of the science. He said, that it was absurd to speak of the animal kingdom as furnishing any analogy with the subject in question, because, whilst the animal being (taking the perfect members as these only which were understood) was but one individual, or centre of vitality, the vegetable is composed of a numerous congeries of individuals, or distinct points of vitality, and therefore the monstrosities of the animal kingdom have no bearing on the question. He would indeed willingly allow that the Creator had made nothing in vain; but as a proof that this fact did not become opposed to Morphology, he cited numerous instances of plants which produce perfect seeds, and re-produce their species, and are yet wanting in some of the parts which are held to be essential, or even indispensable, by anti-morphologists: thus, the Oak, which produces perfect leaves and flowers of its own peculiar nature, is entirely devoid of the corolla, which is present in the majority of plants; and in the Salpiglossis, which, when fully developed, has a very handsome and conspicuous corolla; he had observed a seedling of which the flowers were devoid of a corolla, but had, nevertheless, borne seeds, and produced perfect plants. He entirely repudiated the charge of atheism, which was inapplicable to those who professed the doctrine; they being fully imbued with a sense of the Divine power, and even less atheistical than the florists, who had been and were busily engaged in perfecting the perfection of the Creator. The further discussion of the subject was postponed to the next meeting.—*M.*

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

INGA PULCHERRIMA. Prettiest flowering Inga. (*Greenhouse Shrub*). Leguminosæ. Polygamia Monœcia.—In a genus of plants like the present, abounding in noble trees and handsome shrubs, airy and elegant in their foliage, and bedecked with specious inflorescence, the propriety of bestowing a name denoting superlative beauty upon any individual species may be somewhat questionable. Whatever of hyperbole there may appear, however, in that assigned to this plant, the beauty and loveliness of its characters entitle it to some corresponding epithet to distinguish it; and though there may be other species equally meriting admiration and distinction, these is none more worthy of ranking amongst the fairest ornaments of the tribe. One hundred and thirty-six species of Inga are enumerated by Don in his "System of Gardening and Botany," and it would appear from our catalogues, that fully one hundred of these have never yet graced a British collection. We may, therefore, hope that many, when introduced, will prove useful acquisitions to the stove or the greenhouse. This plant flowered last February in the collection of Mr. Jackson, of Kingston, from whom healthy plants may be procured. Uniting with its superior ornamental qualities a propensity to disclose its beauties at a season when the general paucity of flower induces us to regard every fugitive blossom with a favourable eye, it is still more valuable. It bears a striking similarity in its general aspect to I. kermesina. It has, however, much smaller foliage, and the drooping tassel-like blossoms, though scarcely equal in size, shine with a deeper and more lustrous hue. The irritability common to the leaves of many species of Mimosæ, and especially M. pudica and sensitiva, is also displayed, though to a less striking degree, in the plant under notice, particularly when grown in a warm stove. If the young leaves are pressed roughly by the hand, exposed to a strong current of air, or a sudden depression of temperature, they rapidly contract and fold together, but soon expand and raise themselves again to their usual position. When cultivated in the greenhouse the leaflets never expand, even in the brightest and warmest days throughout the whole course of the winter season. In its cultivation, the chief things to be thought of are the selection of a suitable medium for the roots, to provide a congenial atmosphere in the growing season, and afterwards conditions favourable to a suspension of vegetative activity. A light loam added to an equal proportion of peat and sand, enriched with well-reduced leaf-mould, may be used with propriety. A greenhouse temperature is decidedly most proper during the summer season, and till the autumn is far advanced. In winter it should be kept in the stove, where it may remain till May or June. It is stated to be a native of Mexico, in Loudon's "Hortus Britannicus," and introduced to this country in 1822. The generic title is a South American name adopted by Maregrav, a naturalist who wrote on the Natural History of Brazil, about the middle of the seventeenth century.—*Paxton's Magazine of Botany.*

ODONTOGLOSSUM LÆVE. Smooth-lipped Odontoglossum. (*Stove Epiphyte*) Orchidaceæ. Gynandria Monandria.—Both Mr. Skinner and Mr. Hartweg found this plant abundantly in Guatemala, and sent it home to their friends, so that it is by no means rare in collections. It is not, however, much esteemed, because of the flatness of colour in its flowers. Nevertheless, they have cinnamon-brown blotches on the yellow ground of the petals and sepals; and the lip, which is white, is banded with violet across the middle; besides which, they are fragrant. The name Odontoglossum, or tooth tongue, has been given to these plants because they are usually furnished with strong teeth on the lower part of the lip, and these teeth are not unfrequently very conspicuous. Here, however, they are reduced to a couple of trifling notches, and might be easily overlooked. This species should be potted in turfy peat, and placed in a moist stove. A liberal supply of water should be given during the growing season, and the house should be shaded in sunny weather, in order to keep the temperature as near 80° by day as possible. In winter, like many other bulbous Orchidaceous plants, it requires very little water for a few weeks, but would be much benefited (especially in clear weather) if the house in which it is grown could be filled with steam once a day. The temperature should at that time never be raised above 60° by fire-heat.—*Botanical Register.*

Garden Memoranda.

Dalvey Gardens, near Forres.—On recently visiting these gardens, we were gratified by observing a number of rare and pretty plants in bloom, among which we particularly noticed in the new stove, a large plant of Zygopetalum Mackaii, bearing a number of spikes of flower; the delicately coloured Cattleya Harrisoniæ; the highly fragrant Stanhopea oculata, in fine flower; along with a large plant of Oncidium flexuosum; the butterfly plant, O. Papilio; the beautiful Saccolabium guttatum, producing its graceful raceme of flowers like a pendant feather; Vanda multiflora, with small yellow flowers barred with brown, and the deep yellow Dendrobium chrysanthum, marked in the centre with a dark velvety spot. The beauty of this house was much heightened by the different species of Achimenes. There was also in good bloom the beautiful, bright yellow-flowered Echites suberecta, and the exquisitely tinted Ipomœa Learii. In one of the houses we observed a large plant of Lilium punctatum album, with four flower-stalks, seven feet high, bearing nearly forty beautiful white flowers; a good L. punctatum, with three stalks, six feet high, bearing upwards of a score of delicate tinted pink and white blossoms; and the scarce L. speciosum, with one stalk, four feet high, bearing nine exquisitely beautiful rose and white flowers. In this house there was also in bloom many of the new varieties of Fuchsia now in cultivation, some of which were covered with very large and showy flowers. The open grounds were ornamented with Dahlias, Hollyhocks, &c., just coming into bloom, many of which are fine sorts.

Miscellaneous.

Mutual Indentation of Two Forest Trees.—Near the walk which leads to the flower-garden at Walton Hall, near Wakefield, may be seen an English Elm and a Scotch Fir growing in close embrace. They are now 15 feet in height, and 1 foot 10 inches in circumference at the base. By twisting the leading shoot of one tree annually round that of the other, the trees have become deeply embedded in each other's folds. The Elm being of stronger vegetation than the Spruce, I have taken the precaution of curtailing the lateral branches of the former, lest it should prove too much for its weaker partner.—*Waterton's Essays.*

Insect Revenge.—At Leintwardine, lately, a swarm of bees, which had been brushed off the mouth of the hive, where they had clustered, became so irritated, that they set upon everything in their way, and stung to death 26 chickens and young ducks. The old poultry got out of their road, or they probably would have shared the same fate. After sundry gyrations, and other onslaughts upon man and beast, the night approaching, they returned quietly to the hive.—*Scotsman.*

New sort of Tamarisk.—At Mudjèlibé, or Babel, part of ancient Babylon, there grows on the summit of ruins, which are supposed to have been the suspended gardens of Semiramis, a lonely tree of which all travellers speak. Some call it *cedar*, others say that it is a tree, the like of which is not to be found anywhere else; finally, a very ancient tree, perhaps, even as old as the time of Herodotus. This tree, according to dried specimens, gathered by Aucher, in 1835, is the Tamarix pycnocarpa. Other species of Tamarisk grow in those countries, among others, the Tamarix articulata, which is very common in Asia, as well as Tamarix gallica, which is found almost everywhere. This last species is not rare in the gardens of Europe, whilst the other two are not yet known there. —*Pépin, in Revue Horticole.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

STOVE PLANTS, and indeed all house-plants, have ripened better this season than they generally do, owing to the hot, clear weather, in the end of the spring and through the summer. This corresponds with the treatment generally recommended for some years past, which is—after vegetation has fairly begun in spring, to increase the temperature of the houses, and by way of gentle forcing to assist nature. Plants thus treated, and stove plants in particular, cannot be too cautiously watered late in the autumn. Nothing is now wanted, but to keep the soil from getting quite dry. In dull or rainy weather slight fires should be made in the forenoon, not so much for the purpose of raising the temperature, as for drying the house. Allow a little ventilation, as stoves generally are too much crowded, and so damp that, more or less, air is always necessary to maintain a healthy atmosphere.

Conservatory.—On the contrary, everything in the conservatory should be clean and sweet; the plants should never be crowded, therefore little air is wanted through the ventilators while the plants are at rest; indeed, letting in strong currents of air at this time does a good deal of mischief, by drying the soil in the pots too much, and thus rendering large doses of water necessary when none at all is wanted. Plants in sitting-rooms now require a very different treatment; housemaids will ventilate their rooms as long and as often as they can, and make large fires in cold weather, very much to the injury of plants, which must have water freely every day, and should be changed as often as the stock will permit.

Pits and Frames.—By the middle of September Violets should be planted out in pits, within a few inches of the glass; after they are well watered lay well an inch of very dry soil over the surface, in order to keep down the damp until the plants are firmly established and hauled to confinement. Pots of Mignonette must also be protected from rain; but they should not be kept close. Heliotropes often get too strong about this time, if they are in the open air; when this happens they never flower so freely in winter; a short allowance of water with some covering will soon check them. China Roses of all classes that have been close pruned in August should now be encouraged in pits, and they will soon begin to bloom. Dwarf Nerriums that have been hard forced to make young wood after flowering should be hardened to stand over the winter in cold pits, merely keeping the frost from them.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

Where extensive alterations and improvements in pleasure-grounds are contemplated, the sooner they are proceeded with after this time the better. There are many advantages in commencing early: first, much more work can be done in a given time, now that the ground is in a workable condition, than it is possible to perform after the rains of winter have set in, and not only can much more be done, but it can be performed in a much more satisfactory manner; secondly, by commencing early we have the choice of the nurseries for such plants as are required, and there is a better chance of the transplanted shrubs succeeding, because, if the autumn is mild, they will strike root at once, and if it is not mild they will get so firmly fixed in the ground as to receive little injury; thirdly, new ground work should always, if possible, be got over before Christmas, and all planting should be completed by the middle or end of November. Choice Evergreens, especially if removed from nursery-beds, I prefer transplanting in April, as I have always found them succeed better than when removed in the autumn. Since April last I have removed hundreds of both evergreens and deciduous shrubs and trees, some of them from 10 to 20 feet high, and in full leaf; and dry as the season has been I have not on an average lost more than one in a hundred. The last, and perhaps greatest advantage of autumn planting is, that it sets the gardener's hands at liberty for spring work, which, if anything like high keeping is desired in the grounds, is essentially necessary.

Pits and Frames.—In about another fortnight the season for propagating will be gone by; therefore, where sufficient stock is not already got in, there is little time to lose. Plants that are standing out to be hardened should be so arranged as to be readily covered in case of frost, which may now be expected; and choice plants in beds which it is intended to take up and pot, should also be protected on cold nights.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Tulips.—Seed may now be sown in shallow pans or boxes, covering it very slightly. Continue to make additions to your collection, always preferring quality to quantity. Many fine

varieties are broke in different parts of the country, from seedling breeders, which will drive many old sorts from the amateur's bed. *Carnations.*—Now is a most excellent time to take off and pot layers; if wireworms are in your compost, and your layers are destroyed, who will be to blame, after the repeated warnings given, to look well to it yourself? There is nothing like the grower's eye to detect these mischievous depredators. *Dahlias.*—Cuttings of anything very choice may be struck in a very gentle heat; they will form excellent pot roots for spring. *Pinks.*—Do not delay another week the formation of your beds for next season's exhibition. As we have before observed, very much depends on autumnal planting. *Auriculas.*—Keep these from the heavy autumnal rains, but by all means let them have all the air possible. *Polyanthuses*—May be removed with safety, but the sooner the better.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—More attention, if possible, will be required from this time in regulating the temperature of the Pine pits, as the necessity for using artificial heat increases. Keep the plants in fruit at 68° by night, and give a portion, however small, of fresh air every day, if at all practicable. Syringe the plants occasionally with water at 80°, and look frequently to the state of the soil, as regards moisture. The successions need not be kept higher than 65° on chilly nights. Great attention must be paid to renewing the linings when necessary of pits heated by dung. Those pits stewed heat which have a hot-water pipe carried round them, to dry up damp and raise the day temperature in cloudy weather, so as to admit of a portion of air being given every day, to sweeten the atmosphere and refresh the plants. There is no doubt that dung-heat is the best for growing Pines; but without the assistance of fire the plants sometimes unavoidably experience changes of temperature not favourable to them. Where there is not the convenience of a small boiler to such pits, now is a good time to supply the deficiency.

Vineries.—Do not defer the pruning of Vines intended for early forcing too long, or they will bleed when cut. Vines that ripened their fruit in April last will now break readily with but very slight encouragement. Some old Vines here, which I intend doing away with, are now swelling their buds fast, although they have all the air which it is possible to give them. I will now encourage them to break, and I have no doubt that some very early Grapes may be obtained, as the fruit will be set before the power of the sun has got to its lowest. After the crop is cut, there will be ample time for the young Vines planted in their place to make a good season's growth. I do not, however, recommend commencing to force at this early season, except in similar cases to the above, for it is ruinous to good Vines to excite them to growth at this season. Continue to carry on any alterations or repairs in the Vineries, while the season is favourable.

Peaches.—I again recommend losing no time in forwarding whatever work requires doing in the early house, and particularly in planting fresh trees in the place of any that may be worn out. Make choice of trees for this purpose that are in a bearing state, and that have been moved last autumn. These will certainly bear fruit the first season if taken up now. Peaches and Nectarines planted now in fresh soil, will go on making new roots nearly all the winter. In pruning the trees that have lost their leaves, be careful not to leave them too much crowded; but if the summer pruning has been properly done, but very little indeed will be required now. The Noblesse Peach should not have its young wood shortened or much thinned till after the fruit is set, as it is liable to break badly, and many of the fruit-buds drop off. By leaving the whole of the young wood till the fruit is set, a more regular crop will be insured as well as a better choice of young shoots for filling up the tree. Peach-trees in pots should now be pruned and top-dressed.

Cherry House.—The directions for the Peach-house will also apply to this, except that in planting fresh trees the soil should be of a somewhat lighter nature than for Peach trees.

Strawberries.—If the recently-potted plants have not been removed from the shady situation they were placed in after being potted, it should no longer be deferred, as they require all the sun possible now, as well as a free air to prevent the foliage becoming drawn, and to mature the plants.

Melons.—The weather has been unfavourable for ripening the late Melons, and they must be assisted by having a good top and bottom-heat, and a considerable portion of air in the middle of each day, or the fruit will be worthless.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Strawberry-beds.—Notwithstanding the repeated observations in the *Chronicle* respecting the impropriety of cutting off the leaves, upon the proper development and full exposure of which the maturation of the buds for next season depend, the practice is still extensively adopted, and it is no unusual thing to meet with individuals who proudly contrast the neat appearance of their beds with the somewhat rough aspect of those where the runners have only been removed, the smallest buds singled out, and full exposure given to those remaining. The treatment of Strawberries, as of everything else, should be varied according to circumstances and the object aimed at. The mowing off the leaves will succeed better in light soils, and in warm situations, than it will do on cold, stiff soils, as in the first case the mowing will be earlier performed, and a succession of healthy leaves will be produced, but produced at the expense of the stored-up nourishment existing in the bud. It may also be adopted in those cases where the unworkmanlike practice exists of depending chiefly on the runners of the present season. It is true that abundance of Strawberries may be procured by such a system, but the results of my practice and observation would say, that such fruit is not for a moment to be compared, either in quantity or quality, to that produced by the plants, where their leaves are left unmutilated. Besides, this system of cutting off the leaves renders the plants very susceptible of injury from the first keen frosts. The space between the rows may now be slightly forked, and a little manure put on the first opportunity.

Cauliflower.—Those who prefer August to September for sowing this, may now be getting it planted; where it is to receive the protection of hand-lights they should not be put on until indispensably necessary, as this will prevent much trouble afterwards. The rains we have had will save watering all the newly-planted vegetables, and has afforded an opportunity for tying mats, making tallies, looking after seeds, and putting all the rooms and sheds in good order. If fine weather succeeds, it will be very serviceable to late *Peas* and *Beans*, but if the former are so sown that little rain can reach the roots, they may still require artificial watering, as if the surface is kept moist by rains, and the roots are still in a dry condition, it is very favourable to the production of mildew. All the rain which we have had has wet the ground very little as yet.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—These, from the varying tints of the decaying foliage, now present a beautiful appearance. Look over them, take out some trees in order to make room for others, or plant trees of different kinds in order to improve or beautify the scenery by the diversity of colour; prepare for the thinning and planting season, which is at hand.

Coppices.—Fill up any vacancies with the same, or more valuable "stuff," clear away all that is useless, and trench, hole, and drain the ground where it requires it.

Young Plantations.—Frequently contemplate what should be done in this department before the thinning and planting season arrive. In thinning, whether indiscriminately, as is the too prevailing custom, or in groups or masses, keep each kind by themselves. I would strongly, for various reasons, advocate the grouping system; and in all new plantations let what are designed to become permanent trees be planted in groups, each kind by themselves, intermixed with nurses, some to be taken out and others to be kept low or headed off at certain heights for forming permanent undercover; the Beech, Hornbeam, Silver and Spruce Firs, are excellent for this purpose, particularly in Larch plantations.

Hedge Rows.—Refer to the two last Numbers of the *Chronicle*.

Nursery Work.—Follow the directions in the last week's Calendar.—*W. B.*

VII.—COTTAGERS' GARDENS.

Although the beauty of the garden may now begin to decline, do not cease to keep it equally neat and clean as before, but even more so, if possible. Leisure hours cannot be better spent than in attending to the little plot which, owing to the late favourable weather, still maintains a tolerably gay appearance. Dahlias, which are still blooming well, should have great attention bestowed upon them. Allow no decaying flowers to remain, and keep them neatly tied; clear away the haulm and decayed stems of such vegetables as are no longer useful to the manure-heap, and prepare the ground for other crops. If a sowing of Cauliflower has not already been made, no time should be lost in getting a few seeds put in. Choose the bottom of a south wall for the purpose, where they will probably stand the winter with scarcely any protection. A small sowing of Lettuce may also now be made on a warm border. Keep Strawberry beds free from weeds and runners. If fresh plantations are wanted, they may still be made. Keen's Seedling and the British Queen are the two most profitable Strawberries for a cottager. Those who grow Tomatoes must keep them free from all useless growths; stop them well back, in order to expose the fruit, which is excellent this season, as much to the sun as possible. Be content with an ordinary crop rather than allow the plants to run too far in hopes of obtaining a very large one, which, being late, will not ripen well. Attend to fruit-gathering; on dry days it is better to gather it a little under-ripe, than to allow it to hang on the trees until it is quite ripe, as in that case wasps, which in some parts of the country are exceedingly troublesome, will have a large share of it. For methods of destroying them see another column of to-day's Paper.—*J. M'H.*

State of the Weather near London for the week ending Sept 19, 1844, as observed at the Horticultural Garden, Chiswick.

Sept.		Moon's Age.	Barometer. Max.	Barometer. Min.	Thermometer. Max.	Thermometer. Min.	Thermometer. Mean.	Wind.	Rain.

The highest temperature during the above period occurred on the 28th, 1832—therm. 82°; and the lowest on the 27th, 1830—therm. 34°.

Notices to Correspondents.

*** In consequence of the Editor's absence from London, he has to crave the indulgence of a few correspondents, particularly *Micklewell, E. G. L., A Lady, G. L. C. F., A Regular Subscriber. Nemo, an Old Subscriber, D. O., A. B., A. M., A. W., G. B., William*, until next week.

Blight.—*Rus.*—That which has attacked your Scarlet Runners is doubtless the red spider, for which no complete remedy is yet known.‖

Cardoons.—*J. F. S.*—Your Cardoons have been too early sown. The leaf-stalk is the part used.‖

Celery.—*Inquirer.*—Some earth up Celery by degrees, commencing early; others allow it to grow large, and then at once earth it up, and by so doing the plant acquires greater bulk. The stalks, however, are more tender when their lower parts are gradually covered; but a good portion of top should be left clear till the approach of severe weather, as regards the main winter crop; that for early use, of course, should be fully earthed up a fortnight previously to its being taken up.‖

Clubbing.—*Rus.*—The disease called clubbing certainly originates in the soil; but the grub which causes it sometimes attacks the plants whilst in the seed-bed. Doubtless brick-ash, burned earth, or burned turf, would prove beneficial, as you have experienced it to be. Marl is an excellent application, perhaps the best of any for old garden soil in which the Cabbage tribe is affected with the disease in question.‖

Fig trees.—*Inquirer.*—*Jubo.*—All that your Fig-trees require at present is protection from the early frosts, even if these should be but slight. The foliage of the Fig ought never to be killed by frost; for if this is allowed to take place, then the extremities of the shoots, on which the embryo Figs are situated—all that could be depended on for perfecting fruit in the following season—likewise perish. It is better not to remove the half-grown Figs; they will soon die without wounding the trees.‖

Growing Letters.—*X.*—Excuse us. We do not believe the story. That imagination may *fancy* letters on a Calceolaria flower is possible, but that they should be as plain as if painted is rather too incredible.

Heating.—*Nessicus.*—If you are far north would not the Polmaise plan be worth consideration, combined with a tank for propagation? At all events you must have hot-water pipes for air-heat, as well as a tank for bottom-heat.—*A Young Gardener.*—We have not a word to say in favour of your plan. Why on earth go back to flues? And how do you think you will clean those which are placed under your bed? This scheme has been tried, and always proved a failure. Flues are very bad things in themselves, and detestable as a means of bottom-heating. If you do employ them never expect to see any Pines above six ounces.

Insects.—*A Far-North Man.*—Thanks for the specimens; they are the larvæ of the Lophyrus rufus, allied to L. pini, figured and described in Curtis's Brit. Ent. pl. 54. As they feed generally on the leaves, they seldom do any serious mischief, I believe, in this country, and probably will not make their appearance next year. *R.*—*H. D.*—We must request you to send Mr. Curtis a twig of an Erica with the scales upon it, as your quill contained only a little earth. We fear, however, that you will not be able to extirpate them. *R.*—*W. Jos.*—Many thanks for your pupæ, which we hope to rear, and will then discuss the economy of the Lophyri. *R.*—*Abenezar.*—Your insect is the male Stag Beetle, Lucanus Cervus, which is supposed to wound trees and feed upon the sap; vide Curtis's Brit. Ent., fol. and pl. 490. *R.*—*W. H. H.*—We must refer you to our Entomological article of last week, where you will find the grubs destroying the Cabbage-plants described and figured under the name of Noctua excla-

mationis. *R.*—*s. A. s.*—The Weevils, for which we are much obliged, appear to be the Apion flavifemoratum. *R.*

Names of Fruits.—*A. A.*—1 and 3, Bellegarde, probably; 2, Late Admirable. The Plum, No. 4, which you obtained from Italy, resembles the Quetsche, or German Prune, and was received from the Boiwiller Nursery, under the name of Quetsche d'Italie.‖—*D. P. Q.*—1, Wormsley Pippin; 2, Mank's Codlin; 3, Stone Pippin; 4, Pearson's Plate; 5, Beauty of Kent; 6, Alfriston; 7, Brabant Bellefleur; 8, King of the Pippins; 9, Hollow-crowned Pippin; 10, Blenheim Pippin. Pears: 11, Doyenné Blanc; 12, Passe Colmar; 13, Meoriowi Egg. Peaches: 14, 15, and 16, Royal George.‖—*F. G. H.*—1, Russet Nonpareil; 2, Downton; 3, Spice. Pear: No. 1, Hampden's Bergamot.‖—*Amygdalus.*—1, Appears to be the Bellegarde; 2, Old Newington; 3, Late Admirable. It is almost impossible to distinguish some varieties of Peaches, especially after bearing carriage, without the leaves and size of the flowers.‖—*A Subscriber.*—1, Grange Pippin; 2, King of the Pippins; 4, Monstrous Leadington; 6, Gray Leadington; 7, Dumelow's Seedling; 8, White Impératrice Plum; 9, A sort of white Damson.‖—*T. Davidson.*—Your seedling Plum, small, purple, with a Damson flavour, can be proper only for kitchen use.‖—*R. Headly.*—Your seedling Nectarine is as good as a Newington, and is, like the latter, a clingstone; but such are not now in estimation.‖

Names of Plants.—*G. H. B.*—Goodenia ovata.§—*S. Lee.*—1. Centaurea Cyanus; 2. Medicago sativa; 3. Lychnis dioica; 4. Malva rotundifolia; 5. Arenaria rubra.§—*H. D.*—Not an Epacris, but a Callistemon of some sort, which, without a flower, cannot be named.§—*G. S. Gibson.*—Not Galium spurium, but *G. tricorne*, abundant in some parts of the country.§—*W. G.*—Campanula patula.§—*A Subscriber.*—Crassula tricuspidata and coccinea.§—*Emma.*—Zinnia violacea.—*W. C.*—Hippeastrum reticulatum.—*Tuscan.*—Certainly not. Cupressus etruscum is perfectly smooth.—*B. T. S.*—Your plant, not being in flower, cannot be named with certainty. It looks like Adiumia cirrhosa.—*T. B.*—Aplos tuberosa.—*F. H.*—1. Stigmaphyllon ariatatum; 2. Triopteris jamaicensis.

Pomegranates.—*Ryde.*—The late growth of your plants will no doubt render them more susceptible of cold than they would have been otherwise. It is therefore necessary that they should be more carefully guarded from hard frost when it comes. It will also be as well to shorten back, next March, all the branches which have burst into twigs; there is no fear of their dying. When they have lost their leaves we should transfer them from their old tubs to the new ones, and take the opportunity of renewing their soil, where it is loose, with fresh loam, such as would suit a Peach-border. In order to secure bloom hereafter they must be kept, while growing, in the hottest and most sunny place in the garden; if in front of a south wall so much the better. The flowers hitherto produced were prepared in the hot summer of Paris, and until similar effects shall have been produced on the trees by similar weather, no abundance of flowers can, we fear, be expected.

Potatoes.—*A Subscriber.*—Your Potato is the Purple Kidney, an excellent late variety.‖

Red Spider.—*A Subscriber.*—There is no plan of destroying this pest except by means of sulphur. The best way of applying it is to heat your flues or hot-water pipes, and then, while they are quite hot, to wash them with lime and flowers of sulphur. We fear the white worms you speak of are the grubs of some insect; and if so your soil must all be changed or burnt.

Roses.—*Green.*—What is to be gained by budding Roses on evergreen stocks? That will not make the former evergreen. If you want evergreen Roses you must trust to the China Rose and its allies.—*Octavia.*—If your Roses are transplanted carefully they will take no harm. Shorten the branches after they are removed. We have not made up our minds about reprinting the "Rose Garden." Do not allow this year's buds to bloom this year.

Underwood.—*L. Q. Z.*—The following ornamental evergreen and deciduous plants may be recommended for planting under trees:—Common and variegated Holly, Aucuba Japonica, Laurustinus, Berberis Aquifolium, Viburnum opulus and oxycoccus, Ribes sanguineum, Cornus sanguinea, Leycesteria formosa, common and Portugal Laurels.‡

Vines.—*W. C.*—The circumstance of your Vine-roots being 2½ feet below the surface, and in cold, stiff soil, partly accounts for the berries neither swelling off nor colouring. The great slope of the border has probably occasioned it to be too dry in summer; for borders are generally too wet and cold for the roots of the Vine in winter, and allowed to be too dry in summer. You had better make a fresh border with rich turfy soil, using the surface of the old, which you say has lately been made good, for mixing with the turf and other materials proper to be introduced. Young Vines certainly; those that are 30 years old could not be replanted with advantage.‖

Miscellaneous.—*A. W.*—We would willingly repeat incessantly answers to questions continually asked; but where are we to find room for them? It surely is not asking too much of our readers to consult a few indexes for information which has been very often given. In the particular instance to which you refer we could not repeat the recommendation, the having given it at all being contrary to our rule, and only forced upon us by indispensable necessity. It is very possible that we may be sometimes imposed upon. Who is not? But we are not aware of any recent instance. Do not suppose that we are always ignorant of the authors of facts, which are only signed for the public eye with the initials of the writers. We are much obliged for your good wishes. Our opinion about guano is exactly the same as your own.—*A Subscriber* is answered in another column.‡—*D. W.* will find a select list of greenhouse climbers given at p. 392 of the present year.‡—*A Lady.*—We are unacquainted with any Fig with such a name as the Dough Fig or the Velasca. Very little is known in this country about this kind of fruit. Lindleya grafts readily on the Whitethorn, and will, in all probability, prove quite hardy in South Devon.—*Thomas Hughes.*—See a Leading Article to-day.—*J. W.*—Write to the keeper of the Bazaar. We have no other information than the advertisement.

SEEDLING FLOWERS.

Dahlias.—*W. H. S.*—Your seedling wants fullness in the centre, and the flower altogether wants depth.*

Fuchsias.—*J. P.*—Your seedlings are large, stout, and fine flowers; but the market is stocked with varieties from which it would be impossible to distinguish your specimens; the dark varieties are of no use. Picta, the light variety, is a good flower and worth keeping.*

Lophospermums.—*Joseph Fryer.*—Your seedling is curiously mottled, but it wants brightness of colour; it will always have a faded appearance.§

Pansies.—*F. T. G.*—Your seedling is a flower of good size and substance; top petals deep purple, with a narrow margin of yellow; the lower petals yellow, with good eye.*

Pelargoniums.—*L. L.*—Your seedling is a well-formed and very good flower; it, however, bears too strong a resemblance to an excellent variety in cultivation named Hodge's Oberon.*—*J. R.*—Both your flowers are rather deficient in form. No. 1, which is fine in colour, has the lower petals too long and narrow, and the divisions between are large; in colour, texture, and substance, the flower is of a superior order. No. 2 has richly-coloured top petals, but altogether the flower is rather coarse, the centre somewhat discoloured, and surface of the petals velvy.*

Erratum.—At p. 660, article *Potter's Guano*, instead of "one-fifth guano and four-fifths *night*-soil," read "one-fifth guano and four-fifths *light*-soil."

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, in agricultural districts, many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage; the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet), with directions for applying them.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Grueber & Co., 11, Manesty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKIBBIN'S improved SHEATHING, BOILER, RAILWAY, and other FELT.

*** The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storm; it can also be more easily repaired, and from the simple mode of application recommended, the wet can not percolate through nail-holes, being only fastened down at the overlaps.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

The Agricultural Gazette.

SATURDAY, SEPTEMBER 21, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

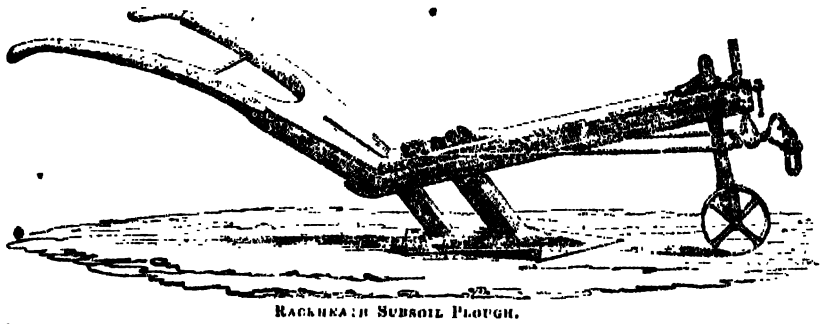
WEDNESDAY, Oct. 2 Flax Imp. Society of Ireland.
THURSDAY, Oct. 3 Agricultural Imp Soc. of Ireland.

FARMERS' CLUBS.

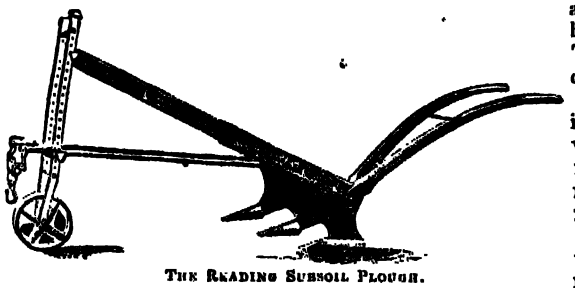
Sept. 23—West Hereford, W. Firle, Fairford, W. Market, Yoxford.
Sept. 24—Framlingham, Isle of Thanet, Rayleigh.
Sept. 26—Richmondshire.
Sept. 27—Halesworth, Hadleigh.
Sept. 30—Chepstow.
Oct. 2—Harleston.
Oct. 4—Collumpton, Abergavenny.

A DESCRIPTION OF THE IMPLEMENTS OF CULTIVATION cannot be better prefaced than by an article on those employed in drainage, for this process lies at the foundation of all good—*i. e., economical* Agriculture. Opportunities will hereafter occur of referring to the draining-plough, the mole-plough, and other smaller tools required in draining. the first is rarely useful, except on the most homogeneous clays; the second is used to a considerable extent on pasture lands—by means of it a very imperfect, and by no means permanent description of drainage is effected; and the others are not individually of sufficient importance to justify the occupation of space here by further allusion to them. Our present object is to describe THE SUBSOIL PLOUGH, which is, strictly speaking, a drainage implement.



Land cannot with benefit be rendered loose, to any considerable depth, if it be wet. The subsoil plough is not useful to the farmer of wet soils; his land must be dry, artificially or naturally, before this implement can be beneficially used by him. We do not wish our readers to depend on a mere assertion of this; but, without defending the statement at any length, it appears sufficiently obvious, that to deepen a wet soil would be to render it almost uncultivable by horse-labour—for draught animals require a firm footing, and this, in wet districts, it will be found, is always preserved for them by the shallow cultivation which experience teaches such lands should receive. And it is not unlikely that the practice of subsoil-ploughing, (or stirring, as it might more properly be called,) which, we find, from some of the County Reports to the Board of Agriculture,* prevailed half a century ago, has died away in those districts where once it existed, because it was unconnected with any efficient system of drainage. It was not till Mr. Smith showed, on his farm at Deanston, the great advantages following the adoption of both these operations together, that either of them obtained that high place in the practice of good farming which they now hold.

MR. SMITH'S SUBSOIL PLOUGH.

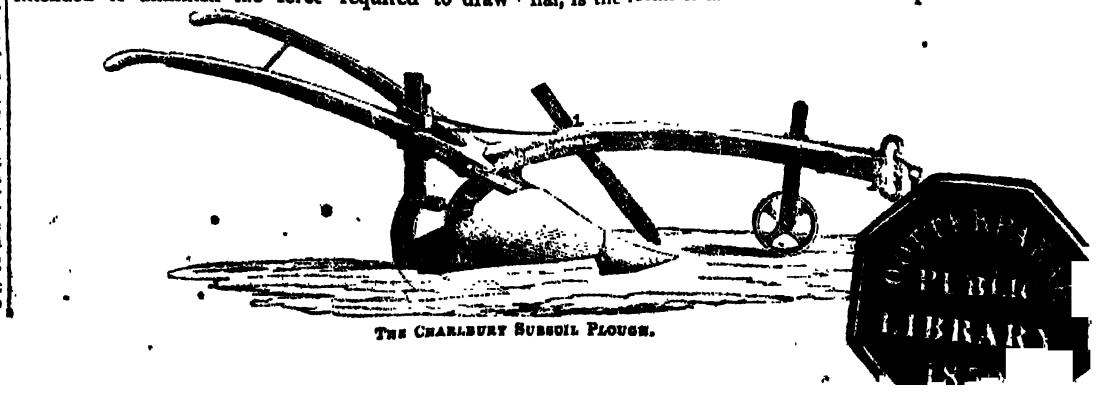


Mr. Smith's subsoil-plough consists of the ordinary framework of a plough, without the mould-board, made strong enough to stand the shocks and the strain to which an implement requiring the force of four or six horses to work it must be subjected. This framework is about 15 feet long. A sole-plate, on which a feather-shaped or pointed sock slips, is attached to it by means of two uprights and a curved coulter. The height of the plough, when held in a working position, from the sole-plate to the beam, is about 22 inches. It is thus enabled to go to a depth of 20 inches. From the furrow side of the sock a spur projects, over which the mass of subsoil cut by the coulter and share is raised and broken, and falls down again. By the action of this spur, and of the whole implement, the subsoil is effectually stirred, without any of it being lifted to the surface. The effect of subsequent deep ploughing, after the action of the air has thus sufficiently meliorated the subsoil, will be beneficial, while without this previous cultivation it would have been injurious. The subsoil-plough requires at least four horses to work it efficiently. The draught in a rather clayey soil was 11½ cwt., going from 16 to 18 inches deep. The draught of the common plough, which preceded it, and turned out the furrow in which it worked, was about 5 cwt., so that the work for the horses was about the same in either case. It is found that the wider the furrow is turned out, the more efficient is the operation. In a subsoil ploughing-match, held at Stirling in 1840, it was found that the best work was done by that subsoil-plough which was preceded by the old Scotch plough, which casts a very wide furrow. It is evident that this does not necessarily imply that the subsoil-plough shall pass along a fewer number of furrows in a given width of land than where the furrow is narrower, for the width of the furrow depends not on that of the furrow-slice, but on the width of the plough, which thrusts the furrow-slice from the fast-land. The expense of the operation of subsoil-ploughing is considerable, varying from 24*s.* to 30*s.* per acre, according to the nature of the land; and it is evident that in rough strong land, where the pickaxe is afterwards required to remove the obstructions which the plough has met with, the expense will be much greater than this. This is a statement of the debit side of the farmer's account of subsoil-ploughing. To find its credit side, he must compare his land as it was—wet or scorched, according to the weather, on which it was wholly dependent—with his land as it now is after the operation, free and friable, dry and open; and he must take the crop he raises now at less expense, too, than formerly; for the land, being drier, is more easily tilled; and he must compare this crop with that he used to raise on the same land. The difference will generally yield a large per centage on the capital he has laid out; the experience of Mr. Brodie, of Abbey Mains, East Lothian, on this subject, is given by Mr. Sullivan in another column of this Paper.

Since the construction of the Deanston subsoil-plough, one of a lighter form, made of wood, has been invented by Sir Edward Straccy, of Rackheath.

RACKHEATH SUBSOIL PLOUGH.

It is used just as Mr. Smith's implement, but the absence of the lateral spur which characterises the Deanston subsoil-plough, must render it a less efficient implement. In this, however, never having seen it at work, we do not speak from experience.



THE READING SUBSOIL PLOUGH.

The same objection exists to another form of the subsoil-plough, of which a figure is given below, which was invented and is manufactured by Messrs. Barrett and Exall, of Reading.

The triple-toothed form of this implement was intended to diminish the force required to draw it. It will be easily seen that when in full work the uppermost tooth is in advance of the second, and that again in front of the lowest, so that the tenacity of the soil and subsoil which hinders the motion of the implement is, as it were, overcome piecemeal, and probably with less resistance than would be presented to the action of any other method. The efficiency of this implement as a stirrer of all the subsoil is, however, far from perfect.

Attempts have been made to combine in one implement the subsoil with the common plough which ordinarily precedes it. Perhaps the most successful of these is that which has resulted in the construction of an implement now manufactured by many parties, which appears and acts first as a common plough worked by two horses, and then, by a simple removal or lifting of the mould-board, is fitted to act as a subsoil-plough, and, in returning, to stir the bottom of the furrow which has just been opened.

The Charlbury subsoil plough, figured below, invented by Mr. Pusey, and described in the first volume of the English Agricultural Society's Journal, is the result of another of these attempts.

THE CHARLBURY SUBSOIL PLOUGH.

* Thus, in the Report of Lancashire, by Dickson, there is the following notice of the "miner, or deep-stirring plough:"—"This is another tool of the plough kind, somewhat similar in its nature, which was introduced into the county nearly about the same period as the trench-plough. It simply consists of a ploughshare firmly fixed to a strong beam, by means of a strong sheath and handle, without any mould-board. It is usually drawn by four or more horses, being made to follow, in the furrow, the common plough, so as to penetrate into, loosen, and stir up the undersoil, without turning it up, to the depth of from 8 to 12 inches below the tract in which that plough had gone." A more accurate description of the way in which the implement is used than is contained in this paragraph of 1813 could not be given now.

This figure is sufficiently instructive as to the nature of its construction; it is not, we believe, found to act well in practice, as the tendency of the attached tooth is to lift the implement behind so as to hinder its efficient action as a plough. Another implement, which probably originated in this invention of Mr. Pusey's, was first exhibited by Mr. Bruce, of Teddington, Stratford on-Avon, at Derby, and is mentioned approvingly by the Society's Judges. It differs from the Charlbury subsoil-plough in the position of the stirring-teeth, which are situated not in the wake of the mould-board but considerably in front, and to the right side of it, so that they work in the last furrow that was opened, and stir the bottom of it just previously to its being filled and covered by the furrow-slice in the act of being turned. This arrangement is said to be effective without at all deranging the action of the implement, or throwing additional labour on the holder. The most efficient mode of subsoil-ploughing is, however, doubtless that recommended by Mr. Smith of Deanston, in which a good wide plough precedes his implement, drawn by 4 or 6 horses.

The advantage of subsoil-ploughing land which has below it a sufficiently frequent occurrence of channels—be they natural or artificial—through which the water held in it may rapidly escape, is unquestionable. The gardener does not hesitate to take every opportunity of deepening his soil, and the farmer's interest is identical with that of the gardener. To increase the fertility of the soil, by rendering a greater depth of it permeable to the roots of plants, and by rendering it independent of our variable climate, should be the object of both; and no means are so likely to accomplish it as subsoil-ploughing *after* draining.

Among the various subjects connected with the practice of Agriculture which offer themselves to us for comment, there is one of great importance, to which we are desirous of calling the special attention of our readers. We allude to the improvement which may be effected in the condition of the agricultural labourer by the general introduction of the allotment system.

To improve the condition of the agricultural labourer is a highly important object—one well deserving the attention of every person engaged in the cultivation of the soil. To remove the depression and distress which too often constitute the lot of himself and his family, and to elevate them in their moral and intellectual character, is a noble project; the accomplishment of which would annihilate the most prolific sources of pauperism and crime, and substitute a cheerful, willing, and able workman in the place of a discontented and depressed one.

Of all the measures which have been adopted for the promotion of this important end, none appears to be more easy of introduction, or more efficient in the accomplishment of its purpose, than the system of allotting to the labourer a small portion of land, which may be cultivated by himself in his hours of leisure, and by his wife and children, without infringing on the time occupied in the service of his master. The size of the allotment should vary with those circumstances of the family which affect their capability to cultivate—such as the age, strength, and leisure of the man, and the number and age of the children. Half an acre may be considered as a medium size.

Provided with such an allotment the labourer has a savings bank—if we may adopt the term—in which he may invest all his spare money and labour; and one of the first results will be that these will flow into the channels thus provided for them, instead of being lost or squandered in the beer-house. The produce of the allotment increases his income materially, and adds to his family comforts; he becomes contented and happy, and regards with pleasing satisfaction the stake which he possesses in the property of the community. A happy effect upon his moral character is the consequence. Placed in a situation of comfort, independence, and contentment, he is more likely to discharge his duties towards society than if in a state of dependence and misery; one is the atmosphere of virtue, the other of pauperism and crime.

The benefit thus conferred on the labourer is productive of great advantage to the community, and to every individual of it. The labourer pays a good rent for his land, and pays it with punctuality. He cultivates it highly by manual labour, and supplies it abundantly with manure from his cottage and his pig. The produce is therefore large. Neither himself nor his family are burdensome to the community, either in a workhouse or a gaol, but instead of dependent paupers or lawless criminals, society obtains orderly and productive members.

The allotment system has been carried out to a large extent in various parts of the kingdom, and the fullest evidence has thus been afforded of its many advantages. The Agricultural Employment Institution, which was established in 1833, turned its attention to this subject, and collected some striking facts, which were published in the form of a pamphlet, but are probably little known. The Institution is since extinct. We extract a few of the most remarkable cases.

"*Colerne, near Bath.*—In 1618, twenty-nine acres of land left in trust for the poor, under the superintendence of the clergyman, were divided amongst thirty families. Prior to the year 1818, this land was let to a large farmer, at only 15*l.* per annum.

"Results:—The tenants and their families have been rendered all honest and respectable; *they have been kept entirely free from parish relief*, and become the farmers' most steady and industrious labourers; the land is so greatly improved by spade husbandry, as to be worth double its value at the time it came into the hands of the poor."

"*Croudall, Hants.*—The allotment system has partially existed in this parish (which contains nearly 1200 inhabitants) since 1819, but of late years has been increased, until 150 acres have been divided amongst 120 labourers, some of it being the very best land, and let as high as 3*l.* per acre, free of tithes and rates.

"Results:—The land is improved, poor-rates are reduced, rents are regularly paid, and new applications for land are made every year. Croudall, which was notorious for thieves and poachers, is now quite altered, and not a man from thence joined in the riots of the agricultural labourers which occurred in the neighbourhood in 1830."

"*Long Newnton, Wilts.*—This parish in 1830 contained forty-two labouring families, all wretchedly poor, the rates paid to them in six months, from October, 1820, having amounted to 206*l.* 8*s.* Every cottager was offered as much land at a farmer's rent as he and his family could cultivate, without interfering with the labour required by the farmers, if they would endeavour to raise themselves above the poor-rates by their own industry. All accepted the offer, except four infirm old men and two poor widows with large families. They had their land on lease, one acre and a half each of arable land; and, when any of them could purchase a cow, were allowed three acres of meadow land, at the rate of 5*l.* 4*s.* per annum for each cow.

"Results:—By the autumn of 1823 every labourer in the parish, except two infirm old men, had not only emancipated himself from the poor rates, but had also punctually repaid the sum of 44*l.*, which had been lent them to purchase tools and seeds; each family had got into cultivation their acre and a half of land; and two or three of them had claimed their Grass-land, having saved money enough to buy a cow; and one family had two cows. The rates for the six months from October, 1823, was only 4*l.* 12*s.* 6*d.* The labourers were reclaimed from idle and bad habits, and became most valuable servants. The widows, before this time, had also taken land, and supported themselves and families without parish relief, although one had six and the other eight children."

"N. Atherton, Esq., of Calne, having come into possession of some property at Kingston, St. Michael's, Wilts, about 6 years ago, immediately let out to the poor forty acres of land in allotments of from three to four acres, at the farmers' rental. This land is well cultivated, and considered to produce 50 per cent. more than any other land in the neighbourhood; *the labourers are raised from a disgraceful state of pauperism* to an honest independence, and the poor-rates are reduced to a comparative trifle."

"*Dauncey, Wilts.*—Some years back the farmers of Dauncey let to the poor labourers of their parish with families, three acres of land each, at 2*l.* per acre; and soon afterwards the late Lord Peterborough built a barn for them, where they could thresh their corn.—Those men struck their names off the parish books, and brought up their families in habits of industry and honesty, and all of them cheerfully paid towards the support of the aged and infirm of the same parish."

What evidence could be offered more striking than this, to prove the efficacy of the allotment system in diminishing—we may almost say annihilating—pauperism and crime, and improving the moral, intellectual, and physical condition of the labourer? What solid objection can be urged to the universal adoption of the system? and why, with evidence such as this, afforded so long ago, do we not find every agricultural labourer in England, who has a wife and family around him, and every single labourer in circumstances to be benefited by it, settled on his allotment of land, an independent and a happy man?

We purpose continuing our remarks on this subject, offering further evidence in support of our views, answering objections which have been raised against the system, and pointing out what we conceive to be the best practical method of effecting its general introduction, and promoting its beneficial operation.—*F.*

ON THE BEST SPRING CROPS FOR FOOD.

[The following paper was read by the Rev. R. Mounts, of Eatington, at a late meeting of the Farmers' Club, at Stratford-on-Avon.]

The points for consideration are—the earliness, quantity and quality, cost of production, and the influence on the succeeding crops of the different kinds of artificial spring food for cattle.

The various sorts may, perhaps, be comprised under Lucerne, Rye, Rape, Rye-grass, Italian Rye-grass, Trifolium Incarnatum or Annual Crimson Clover, Red Clover, Cow-grass, Winter Barley, Cow-cabbage, and Winter Vetches.

Lucerne may be managed in two ways:—Either by preparing a good piece of land, got quite clean and well filled with manure, and reduced to as fine a mould as possible, and drilling the seed, in April or May, from twelve to eighteen inches apart. It should not be sown too early, for its first growth being very delicate, the late frosts in the spring will destroy it. And I should give the preference to eighteen rather than twelve inches, because you can then run the plough between the rows at the end of autumn, and thereby afford a greater facility for cleaning it early at the beginning of the year; and the greater distance also enables you more readily to manure it. After the first cutting, if the spaces between the rows be well hoed and cleaned, it will add much to the growth of the plant. By adopting this plan, supposing Lucerne sown this year, it will be fit for the first cutting in the middle of April next; it may be cut twice or even three times in the first year, and then it will bear cutting five or even six times. Or should this be thought too expensive and troublesome a process, it may be sown broadcast, and harrowed in with Barley, in the same manner as Clover and other artificial Grasses are sown. The quantity of seed should be about 20 lbs. an acre. A field of 11 acres so sown, was mown three times the first year; in the second, it supported from the first mowing, with a small addition of Oats, 30 horses for seven weeks; from the second, 20 horses for seven weeks, without anything else; and from the third, with a small addition of Oats, 20 horses for six weeks. The value of the produce may be estimated at 11*l.* an acre, after deducting all the expenses, rent, and other charges. In the third year it maintained 35 horses for eight weeks, with a small addition of Oats, from the first mowing; from the second, nearly the same; and from the third, although not so productive, yet it was of great value and benefit, on a farm where there was little pasture. It would be easy to adduce many other instances of the productive power of Lucerne. This plant will stand and grow vigorously for 10 or 12, or even 15 years, if nurtured with soot, malt-dust, farm-yard manure, or guano. It produces a great deal of milk in cows and ewes, and it is highly relished by them. It should be cut just before it has come into blossom; and being mown on the preceding evening, it should be removed for use on the following day. Should it be objected that it is a long time in coming to perfection, it may be answered that it is not more so than Clover; and that this "plant of plants" is a giant from its infancy, advancing from strength to strength. There are many varieties of it, but the purple-flowered is the most profitable to the cultivator. It ought to be added, that it may be made into hay, and forms excellent fodder; but it is much better adapted for what is called *soiling*. This most valuable Grass is best cultivated on a good, dry, warm Barley-soil; still it answers very well on a stiff clay, as I have proved by my own experience, and that of a neighbour, on a similar land. Whenever the land returns to the ordinary rotation of crops, it has been found more congenial to production. It has been stated by one of our most intelligent and practical farmers, "that no farm, if it has a suitable soil, should be without Lucerne, in the proportion of one acre (at the least) to every four horses."

Rye is the earliest Grass used as spring food for cattle, next to Lucerne; and this, together with its bulk, forms its chief recommendation; for, unless cut quite young, it is not much relished by cattle. It flourishes on a poor sandy soil or heathy land, where other Grasses would not grow. In the work on British Husbandry, published by the Society for the Diffusion of Useful Knowledge, it is stated that the soils most appropriate to the growth of Rye are those that contain the greatest proportion of sand; and, on the authority of Von Thaër's "Principes Raisonnés d'Agriculture," that it is the only Corn which can be grown upon land which is composed of a mixture of more than 85 per cent. of sand with other earths. The preparation and culture of Rye are essentially the same as for Wheat, than which it is much more hardy, but infinitely less valuable. Within the memory of man, it formed a chief part of the food of the poor of this kingdom, as it does now in the North, and other parts of the Continent; but I fancy the use of it with us, after having been accustomed to good Wheat bread, would occasion a good many *wry* faces. It should be sown at the latter end of August, or early in September, in the proportion of three bushels and a half to the acre. The land should have been previously manured. It may be sown either broadcast or in drills, but the latter is preferable, as it affords an opportunity of hoeing and cleaning the land. Being a hardy plant, it will stand the winter, even when very severe indeed. In a Prize Paper in the Journal of the Royal Agricultural Society, it is stated in reference to the management of Rye—"So soon as the Wheat is cut in the autumn the plough should be set to work. This may be done even before it is carted, during the mornings of harvest. A single ploughing is given, and a very slight dressing of any kind of short manure. In some cases, where the farmer

lays on his manure in the autumn for Turnips the ensuing year, it might be better to lay it on before the ploughing. It should be remembered that the slight dressing should not at all be considered as given to the Rye; in reality, it becomes incorporated with the soil, and more intimately mixed with it than by the ordinary mode of spreading it on in the autumn, and any part of it which the Rye may abstract, will be more than compensated by the droppings of the stock, and the carbonic acid gas which they evolve while consuming it, and which the soil more readily absorbs in the spring than in any other part of the year, evaporation going at that period to a much smaller extent than in any other. The advantages of its cultivation are summed up thus:—Provision of excellent green food is made at a season of the year when, of all others, it is most wanted. It is produced without sacrificing any portion of the usual rotations pursued on a farm, and with little extra labour; nor does it interfere with the management of any preceding or succeeding crops. It will grow on any soil, but it is especially calculated for poor loose land, when every other green esculent is more or less uncertain. It will bear any degree of frost to which our climate is subject, and is sufficiently hardy to defy the effects of the coldest situations in the country, being there cultivated instead of Wheat for a corn crop, from necessity. It is as inexpensive, or more so, than any Grass or leguminous plant. It is readily consumed by stock, especially young animals. It improves rather than deteriorates the soil upon which it is grown. On the other hand, it is only fair to state the observations of others in answer to these high praises. Loudon remarks that husbandry must be bad or unfortunate which requires the necessity of having recourse to it. The opinions of practical agriculturists, so far as I have been enabled to obtain them, are divided. From one I find that, after several years' trial, he has at length abandoned the use of it, from a conviction that it injures the succeeding crop; and that he could always tell, to a yard, from the appearance of the following, where the Rye had preceded it. Another considers there is something poisonous in its nature to other plants, and that he has invariably found the wire-worm most destructive after Rye. From others I have been informed they always grow a certain portion on their best land, and they are satisfied that the early and abundant quantity of green food it supplies is of the greatest value. It may be matter for consideration in the present peculiar season, whether it would not be advisable for the farmer, at all events this year, to supply himself with this earliest food for his cattle, in default of Swedes, Hay, and indeed, Bean and Barley straw.

(To be continued.)

PROPER TIME TO REAP WHEAT.

The discussion and remarks in some of your late Numbers respecting the best time to harvest Wheat as regards its state of ripeness, has recalled to my remembrance a circumstance which occurred some five or six years [illegible] was visiting a friend in an excellent Wheat-growing district beyond Hounslow, and when conversing with a neighbouring gentleman in whose Wheat-field we were walking, my friend remarked that his piece of Wheat was the forwardest thereabouts, and would be fit to cut in a fortnight. The gentleman said he meant to cut early, as he had understood was often done in parts of Hertfordshire, the millers liking the Wheat all the better for it; and he intended to begin on Monday week. Upon which I remarked that if the grain had ceased to derive nutriment from the straw it might be cut to-morrow, and that it would be easy to ascertain that by examining the thread-like connection of the grain (which I shall call the umbilical thread) to the receptacle, whether the grain had ceased to receive nutriment. Whereupon we first searched for and found at the edge of the cart-way a plant in a quite green and growing state, and examining it, saw that the umbilical thread was in a healthy and growing state, and the grain still milky. We next selected several ears from the crop (not the ripest), and on examining them saw that the umbilical thread was in a withered state, and incapable of conveying nutriment. Afterwards we selected some of the ripest ears, and saw the umbilical thread quite withered and dry. But these ripest ears were far short of being dead-ripe. The gentleman said, "This examination has convinced me, and I will begin to-morrow." He did so, was satisfied with the result, and continues the practice. His immediate advantage was that he was enabled to prepare his land and get a good crop of mouse-tail or stubble Turnips. The harvest of that year was generally prolonged by very rainy weather, and in about a month after the examination I saw his Turnips being hoed and a neighbour's sprouted Wheat being carted on the same day. Now there are many reasons why Wheat should be harvested as soon as it can be without loss of quantity or quality of the grain; and I will suppose that it may be, and ought to be, done at least a week earlier than is usual by the present general practice, and then the following may be some of the advantages to be gained:—viz., a week's time in operating upon or cultivating the land, in consequence of the crop having been so much the sooner cleared off; the avoidance of a week's plunder by sparrows, other cone-billed birds, and feathered game; which, in consequence of being deprived of a week's corn-food, may confer a benefit by feeding on the seeds of weeds, such as Polygonum aviculare, and other Spergula, instead; less grain will be wasted by scattering, as ears are less liable to be broken off and the chaff less liable to loosen, than when fully or dead ripe; the Straw must be of better quality for every purpose. If the crop of Wheat should be thin, then, if seeds should have been sown or the field foul with weeds, there will be a week's less growth of green rubbish to retard the drying of the Straw in sheaf; and if the crop of Wheat should be heavy (which would as a matter of course half starve any seeds sown), then the young seeds would a week sooner begin to gain strength against the winter. I am not a practical farmer, and for that reason cannot precisely say what all the advantages would be, but I hope some of your correspondents will enlighten your readers on the subject. I do, however, know a little of botany, so far as English plants are concerned, and though still less of vegetable physiology, yet I venture to assert that the plan of examination of the umbilical thread will be a sure guide. —*J. C. X.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

[The communications of the two past weeks from Mr. Sullivan, on the operations of the harvest, were published in order that they might be seasonable, before his previous papers on Tillage operations were concluded. The following is the last of the latter series.]

Fallowing.—Although the practice of fallowing has existed from the earliest ages, it appears to have been entirely unknown in Scotland till about the commencement of the last century. The singular means by which it was introduced into East Lotnian, and the unfavourable light in which the practice was there first regarded, are thus given by Somerville in his Survey of the County, drawn up for the Board of Agriculture:—"Two persons of high respectability are mentioned as being the first who followed the practice; the one a proprietor, the other a farmer. The proprietor was the Right Hon. Thomas, sixth Earl of Haddington, who set the example upon his own estate. The farmer was Mr. John Walker, in Beanston, as we are informed from respectable authority, who took the hint from some English travellers, while they spent a night at his house, and with whom he had a good deal of conversation upon the subject, so much to his satisfaction that he made an experiment upon six acres the following summer, which he carried through in spite of the animadversions of his neighbours, who were divided in their opinions as to the sanity of his mind or the stability of his circumstances. The result of the experiment gave them a better opinion of both, and the return was so abundant as to induce him to extend his next year's fallow break to twenty acres; soon after which the practice began to spread, and so early as 1724, fallowing upon all the deep strong soils was common throughout the county."

The practice of fallowing thus soon became general throughout East Lothian upon all kinds of land, but the extension of furrow-draining and of drilled crops, which admit of considerable after-culture, has greatly contributed to render bare-fallowing less frequently indispensable upon strong adhesive soils, and altogether unnecessary upon those of a light friable description. The land in this county is too high rented and too valuable to devote any portion of it unnecessarily to an entire year's cultivation without producing any immediate return; fallowing, therefore, is now almost exclusively restricted to the strong cold adhesive clays, which have not been yet properly drained, and on which the cultivation of Turnips would be very unprofitable in many seasons, and most laborious and expensive in all; or to land which has become so much infested with Couch-grass (Triticum repens), Knot-grass (Arrhenatherum avenaceum), and other weeds, that their complete destruction could not be effected while preparing it for green crops. The extension of the culture of drilled crops has, no doubt, greatly diminished the extent of land annually under bare fallow; but for many reasons, which it is unnecessary here to specify, these crops have not entirely superseded the process, and are not likely to do so for a considerable time to come. Wheat, the staple crop of East Lothian, is the most valuable production of our strong heavy soils, and for it summer fallow evidently affords an excellent preparation; but independently of this, another and perhaps a stronger reason for annually devoting a certain portion of the farm to fallow, arises from the fact that almost the whole of the operations connected with the process are performed at a time (from the conclusion of Turnip-sowing till harvest) when the men and horses, at least the latter, would be otherwise comparatively idle. Although strong, stiff, adhesive clays—the only description of land upon which bare fallows are held to be indispensable—derive undoubted benefit from aeration during the summer months, yet no farmer here ever thinks of sacrificing so much rent and labour in fallowing land merely to afford his men and horses constant employment, or to give the soil rest and the benefit of exposure to the atmosphere; but when a field, or some part of it (for an entire field is seldom fallowed indiscriminately), becomes, after a course of cropping, excessively foul with root-weeds, bare or naked fallow is resorted to as the only effectual means of extirpating the greatest enemies with which useful crops have to contend.

The first or winter furrow for fallow is seldom given until the other stubble land intended for green crops has been ploughed. Either of three methods of ploughing is adopted, according as the land may be in a wet or a dry condition. In wet retentive soils, the ridges are either gathered up or cloven out into halves, keeping the furrows open in order to preserve the land in a dry state in winter; but the general mode of ploughing is casting.

The second ploughing is sometimes given after the spring seed-time is past; but unless the weeds happen to be very numerous and luxuriant, it is most frequently delayed until the Potatoes and Swedish Turnips are sown. If gathered up before, the ridges are now cloven down, and *vice versâ*. This ploughing is also not unusually made in a direction crossing the ridges, but in whatever manner the land may be ploughed, it remains in that state until the Turnip-sowing is completed. Should a fall of rain, however, occur after a continuance of dry weather, advantage is taken of it, and when the surface becomes sufficiently dry again, it is harrowed with facility into a fine state, which effectually disengages the weeds from the soil and exposes them to the atmosphere.

As soon as the Turnip-sowing is finished, which is usually about the end of June, the working of the fallow is again resumed. After the weeds, brought to the surface by previous operations, have been gathered off, the land is ploughed in a direction crossing the former ploughings, and as deep as the strength of the horses can accomplish. Deep ploughing is deemed indispensable at this stage of the fallowing process, not only to increase the depth of active soil, but also to bring to the top the roots of all vivacious weeds. After being ploughed the land is repeatedly harrowed and rolled; the grubber is also employed with effect at this stage, in dragging to the surface root-weeds remaining in the soil.

As the great object is the thorough extirpation of weeds, the utmost attention is bestowed, and considerable expense incurred upon their collection. The quickens, as the roots of the Couch-grass and other weeds are termed, are disposed of in different ways, according to the state of the weather and the inclination of the farmer. When the surface admits of being reduced to a fine tilth, the strong vegetative powers of the root-weeds thereby exposed to the weather, are frequently destroyed by the powerful heat of a July sun; and in this case they are ploughed down again into the land with safety, economy, and advantage. But the long continuance of dry and warm weather, requisite to destroy Couch-grass, seldom occurs here; and hand-picking, tedious and expensive though it be, is therefore the most general way of getting rid of the enemy. After being gathered the weeds are sometimes burned, and the ashes spread upon the surface; but the usual, and perhaps the most judicious practice is, to cart them to some convenient corner of the field, to be afterwards formed into a valuable compost with quick-lime.

In most cases the land is a second time cross-ploughed, reversing the last furrow-slices, well harrowed and rolled, and any weeds which may still appear are hand-picked as before, after which it is, in ordinary cases, perfectly clean; at all events the ridges are now formed in order to provide against wet weather. They are always gathered up, and every attention bestowed in giving them the necessary and uniform degree of curvature. The original ridges are usually followed in marking off the new ones; but if it be desirable to alter their direction or breadth, this is the proper time for doing so.

The application of manure is the next operation. The usual practice is to convey the dung to the field some time before it is required for use, in order to undergo the necessary process of fermentation, and to have it at hand, but when the field lies contiguous to the farm-offices the dung is commonly prepared in the yards. In either case it is carted along the ridges, and pulled out by a man with a dung-drag into equal and equidistant heaps, proportionate to the quantity allowed per acre. To facilitate and insure accuracy in spreading, the middle of each ridge is sometimes lightly rolled. The ploughs follow close upon the spreaders, in order to prevent any loss arising to the dung from evaporation. Lime is also frequently applied to fallow, with or without dung: it is scattered upon the surface and ploughed in with a light furrow, and incorporated with the soil by the action of the harrows. Many farmers consider this to be the most judicious period for the application of lime to the land.

In ploughing in the dung the ridges are gathered up again, by which an increased degree of curvature is imparted to them, or cast by ploughing two ridges together. In either case the furrow-slices are taken broad and shallow in order not to bury the dung too deep. This ploughing generally concludes the fallowing process, nothing more being done with it until seed-time, when it receives the last seed-furrow. Instead of giving the seed-furrow in the ordinary manner, some farmers plough the ridges into small drills about 10 inches apart. This is what is termed ribbing, and its object is to prevent the throwing out the plants in winter, by affording a good cover to the seed. The preceding operations are in most cases completed about the end of July or early in August if the season have proved favourable, but the working of fallows is often continued during harvest.

Land is generally fallowed after a crop of Wheat or Oats, but when a Grass-field happens to be in a very dirty and unthriving condition, it is in many instances ploughed up during the summer, cleaned and otherwise prepared for Wheat to be sown in the succeeding autumn. Wheat usually precedes and succeeds the summer fallow. Many farmers have found, however, that the young plants of that crop are very liable to be thrown out of the soil by the influence of the winter frosts, when sown on fallows; it is not uncommon, therefore, to grow Oats or Barley instead of Wheat on bare fallows, where the soil is of that strong clayey character so much affected by alternate frost and thaw in winter.

I have now briefly detailed the general routine of fallowing pursued in the best-conducted farms in this county; but the nature of the season, the quality and condition of the land, and other circumstances, often render it expedient to vary the mode of procedure. As the leading objects sought to be attained by fallowing are the effectual extirpation of weeds, and the minute

pulverisation of the soil, the course of management must be varied according to circumstances, but the different operations persevered in till the land is rendered perfectly clean, and has acquired a certain degree of mellowness. No rules can therefore prescribe the exact number of ploughings, harrowings, &c. to be given; all these are regulated by the weather, and the nature and condition of the soil. The present season has been peculiarly favourable here for cleaning the land, and executing all the operations connected with fallowing.

Subsoil Ploughing.—Although the utility of subsoil ploughing, in connection with thorough draining, as a means of improving stiff clays, incumbent on retentive subsoils, is beyond a doubt, it is scarcely at all practised by the farmers in this county. With the view of ascertaining to what extent the operation is really beneficial, the East Lothian Agricultural Society offered, in 1837, the liberal premium of 21*l.* for the best Report of Experiments on Subsoil Ploughing, as compared with common ploughing. The prize was competed for, and obtained by Mr. Brodie, of Abbeymains, near Haddington. The land selected by Mr. Brodie for experimenting upon had been previously drained in every furrow, 18½ feet apart. It was fallowed in the early part of summer, and alternate portions of the field subsoil-ploughed along the ridges to the depth of 16 inches, immediately before applying the dung and giving the seed furrow. These experiments extend from crop 1838 to crop 1843, both inclusive; and from Mr. Brodie's valuable Report it appears that, although the produce of the first crop (Wheat) was not greater upon the subsoil-ploughed land than upon that ploughed in the ordinary manner, yet the increased produce of the last three years has more than compensated for the trouble and expense attending the operation, as the following summary of the results of the experiments shows. It may be proper to observe, that after the first crop the field was pastured with sheep for two years, and then ploughed up in 1841 for Oats:—

Increase in Oats of 10 bushels per Scotch acre, at 2*s.* 6*d.*			£1	5	0	
6 cwt. Straw, at 1*s.* 8*d.*			0	10	0	—£1 15 0
On Beans of 3 bushels, at 4*s.*			0	12	0	
Straw, 1½ cwt., at 2*s.*			0	2	6	— 0 14 6
On Wheat, of 2 bushels, at 6*s.* 6*d.*			0	13	0	
Straw, 5 cwt., at 1*s.* 8*d.*			0	8	4	— 1 1 4
						3 10 10
Expense per acre of the operation						2 0 0
Profit per acre on the rotation						£1 10 10

The manner of performing the other tillage operations, such as harrowing, rolling, grubbing, horse-hoeing, being the same in this as in other parts of Scotland, does not require any further notice in this place.—*T. Sullivan.*

ON MINERAL AND INORGANIC MANURES. No. XXVI.

By Professor Charles Sprengel.

c. Peat-Ashes.—If we consider that the ashes of the different sorts of peat are composed of different mineral substances, mixed in very varied proportions, and that there are amongst them substances either most nutritious to plants, or such as decompose the humus, it will be easily seen why their use as manures is at times very beneficial, whilst at others they avail nothing, nay, even are hurtful to the crops. The difference between peat and wood-ashes consists especially in their great amount of silica, oxides of iron and manganese, and gypsum; moreover, they never contain carbonate of potash, which is to be found in all ashes of wood and other plants, because if they contain potash, it is always combined with sulphuric acid. It is gypsum, chiefly, which constitutes their value as a manure, which, however, has been hitherto taken no notice of.

Those sorts of peat which have a small specific weight, and are of a light-gray colour, are considered the best, whilst the red are considered worth little or nothing; still these criterions are very deceptive, as at times the light and gray coloured manure much less than the red and heavy ones. Whether peat-ashes will be a good manure can be decided only by experiments on the fields, or chemical analysis, of which the latter is the surest, because experiments on the field may be accompanied by circumstances which will prevent the perfect action of the ashes. I have examined many sorts of peat-ashes—both such as produced very little or no effect, as well as such as many years' experience has proved to possess great fertilising power, amongst which latter were several famous Dutch peat-ashes. I place here the results of these analyses, as they not only best explain their action, but as they can serve agriculturists as a means of judging the value of such as they have at hand.

1. *Dutch peat-ashes*, of acknowledged best quality (gray) 100,000 parts consisted of

47,140	parts of	silica.
4,446	,,	alumina.
6,592	,,	oxide, and a little protoxide of iron.
1,000	,,	oxide of manganese.
13,634	,,	lime, partly united with silica.
4,940	,,	magnesia ditto.
0,200	,,	potash combined with sulphuric acid.
1,013	,,	soda, mostly combined with chlorine into common salt.
7,200	,,	sulphuric acid, combined partly with lime, partly with potash and soda.
1,092	,,	phosphoric acid, mostly combined with lime, partly also with iron.
1,144	,,	chlorine combined with soda into 1,907 parts of common salt.
4,099	,,	carbonic acid, combined with lime and magnesia.
6,600	,,	carbon and remains of peat.
100,000	parts.	

2. *Dutch peat-ashes*, inferior quality (gray) 100,000 parts consist of

55,920	parts of	silica.
3,448	,,	alumina.
5,376	,,	oxide of iron, and a little protoxide of iron.
4,340	,,	oxide of manganese.
8,648	,,	lime, partly combined with silica.
1,560	,,	magnesia ditto.
0,228	,,	potash.
3,855	,,	soda.
6,446	,,	sulphuric acid, combined with lime, soda, and potash.
0,833	,,	phosphoric acid, combined with lime and iron.
6,354	,,	carbonic acid, combined with lime and magnesia.
2,992	,,	chlorine combined with sodium into common salt, and with potash into chlorate of potash.
100,000	parts.	

As both these sorts of peat occur in the vicinity of the sea-coast, it is more than probable that their great amount of common salt owes its origin to salt water. They are conveyed from Holland to Belgium, where they are very important for the growth of Clover, as it is believed that it could scarcely be well reared without the Dutch peat-ashes, which, however, *would* be the case, without any doubt, if it was manured (instead of the ashes) with gypsum, common salt, bone-dust, and some other mineral substances, which are to be found in the ashes. Great expense would probably be thus saved. Still the Belgians believe that the peat-ashes contain a substance unknown, which greatly improves the growth of plants. Besides Clover, they use this manure in Belgium for Rape, Potatoes, Flax, Peas, &c., but never for *Barley*, which consequently, the great amount of gypsum seems not to benefit.

GEO-AGRICULTURAL NOTES ON SOUTH GLOUCESTERSHIRE.

(*Continued from page 628.*)

New Red Sandstone.—This formation, occurring as it does almost exclusively along the sides of the hills and highlands capped by the lias, does not cover any very great portion of our district. The beds of which it is composed are of three kinds, sandstone, red marl, and magnesian conglomerate. The first of these is the least extensive of any. It occurs in a narrow band, overlying the marl along the edge of the coal strata, which it also covers between Stapleton and Winterbourn by Frenchay and Hainbrook. It is a sandstone of a dark-red colour, much more crystalline in its appearance than the indurated marls of the second member of the series. It frequently contains small siliceous pebbles, or rounded masses of flinty matter. It is a soft stone when first quarried, but acquires hardness on exposure to the air, and is then used as building-stone. A yellow sand occurring in this member of the series is dug at Bristol, and sold for the purpose of strewing on the floors of cottages. The red marl of the new red series occurs along the edge of the hills capped by the lias. Thus, from Henbury, where it overlies the magnesian conglomerate, we trace it along the edge of the highland by Over, Almondsbury, Elberton, Lyttleton, and Oldbury, where the tract is of considerable width. A section from this spot towards Thornbury, shows that here also it overlies the strata of the magnesian limestone, on which that town is built. From this its western boundary, which has been all along its junction with the alluvial deposit, it proceeds in a very tortuous course, by Rockhampton and Hill, to Berkeley, where it overlies a sandstone of the old red series. The junction-line of the two runs from Berkeley, south by Stone-common, under the edge of Whitecliffe-park, by Falfield, to Moreton, where it again overlies the dolomitic conglomerate. The junction of the marl with the clay of the old red sandstone from Berkeley to Moreton is very obscure; indeed, in tracing it on the map, one is guided more by the undulations of the surface than by any sectional appearances. The red marl occurs also in the neighbourhood of Newport, where it joins on the old red sandstone and the lias, overlying the one, and being overlaid by the other. I have already described the line of its junction with the lias from Rayuham-fields to Wickwar, where it terminates in a long narrow valley, at the bottom of which a bed of magnesian limestone is exposed. In the marl at Wickwar a bed of strontian occurs; a section of it is seen on the road-side below the church.

From Wickwar a narrow band extends as far as Bury Hill, where the strata of magnesian limestone again appear. From Chipping Sodbury, where it again commences, it extends along the edge of the hills under the lias, by Westerleigh and Liston to Wick, where it surrounds Home-apple-hill, and passing down both sides of the Golden Valley below Wick, leaves an open space in which the rocks of the coal strata occur. This band extends below the edge of the lias, from Keynsham westwards as far as Bristol, the greater part of which is built on it. From Bristol it runs by Stoke Gifford as far as Itchington, bounded on the one side by the lias, and on the other by the band of sandstone we have just described.

At Aust the section of these marls there exposed contains in the lower part of it a great quantity of gypsum, which is arranged in layers corresponding with the planes of stratification, and, being connected together by vertical veins and fissures, a reticulated appearance is presented. No use is made of this gypsum in an agricultural way, though its value as a fertiliser has been fully proved. The clay of this bed is used for brick-making near Winterbourne, for which purpose it answers admirably. The clay in its immediate vicinity on the lias formation, although stiff, and apparently good for the purposes of brick-making, is too calcareous, and would, after burning, speedily crumble, in consequence of the slacking of the lime formed.

The Dolomitic Conglomerate, the third member of the series, is most irregularly distributed over the surface of the district. The chief portions of the county, however, which it covers are near Thornbury, and in the Vales of Henbury and Westbury. Near Thornbury it covers a district two miles long and three quarters of a mile broad. This rock consists in general of fragments of the older rocks, mountain limestone, old red sandstone, and millstone grit, varying in size from that of a nut up to that of the human head, and cemented by a yellowish or a red-coloured mixture of the carbonate of lime and magnesia. It varies considerably in appearance. Thus, in the Thornbury district, while at Rockhampton it is so hard and splintery that it is difficult to form a hand specimen, near Thornbury it consists of large rounded masses, chiefly of mountain limestone, hardly kept together by an earthy cement.

The Agricultural Character of this formation differs considerably on the three members of which it is composed. The soil on the first of these is of a remarkably red colour; it is a light sand. Near Hanbrook it is of a purple-red colour. When taken in the fingers it soils them like a mass of paint. This land is wholly arable; where shallow, as is generally the case, it is wholly dependent on the weather. The season cannot be too wet for it. Even on this land, however, drainage has been attended with benefit. The general rotation followed, when any system at all is adopted, is the four-field course of Wheat, Turnips, Barley, seeds; but here, too, whenever land has by this management become sufficiently in heart, this rotation is left for one more severe. Thus, after Barley, seeds are taken, which are, during the first year, mowed and then seeded; during the second year depastured and broken up for Wheat; after Wheat Barley is taken; then Turnips and then Wheat again, which is followed in the usual way by Turnips, Barley, seeds, and so on. This is the least injurious of the departures from the regular course; for cases occur in this neighbourhood where land in good condition has been cropped during successive years with Wheat, till exhausted. Turnips and Swedes are always sown broadcast. Mangold Wursel, which is far from being generally cultivated in the county, I saw growing on this soil, for which it is admirably suited. The gritty nature of the soil, by admitting the action of the atmosphere, causes the rapid decomposition of the manure in it, and thus fits it for the growth of bulbs and tubers requiring large supplies of nourishment. The lightness of the soil on this rock renders it very easy of cultivation; in this it is greatly superior to the soil on the marl. The surface of the marl being generally exposed on the side of hills, has an undulated appearance; this renders the soil easy of drainage, and the greatest improvement might be effected in this way, over the whole of the district. It is chiefly in pasture—not above one-sixth is under arable culture. The fields are not large, and they are frequently crowded with trees. Both the Oak and Elm flourish here; the finest Elms in the county occur on this formation, near and in Stoke Park.

When so small a portion of the land is arable it is seldom cultivated on any fixed system, and it is only in farms that are almost wholly arable that any regular rotation of crops is adopted. The kind of Wheat sown is the old Red Lammas, or for a spring Wheat, the White Essex. These two, with the Blue Cone for the stiff clays on the lias, are the three standard Wheats in this district, and, indeed, over the whole county. Between the sandy and clayey strata of this formation, I went over several fields of a deep sandy loam, either produced by the mixture of the two, or due to the disintegration of a stratum peculiar to itself. The land here is of a most valuable kind, combining the good qualities of that on either side of it; wet will not sour it—heat will not injure it. It is admirably fitted for the growth of Turnips, of Wheat, and of Oats and Barley. Little of this marl is drained; the pastures during winter are accordingly soaked. The establishment of a tile-work near Winterbourne by Dr. Fox, and the adoption by him of a system of drainage on his own farm, will, it is to be hoped, be productive of good. The soil on the dolomitic conglomerate, the third member, near Thornbury, where the rock has an earthy character, is of a light sandy nature. Near Bristol and Wick, where beds of clay occur in the rock, it is a stronger soil, and more fertile. It is there almost entirely pasture. In the neighbourhood of Thornbury about one-third is arable; the soil is frequently very shallow and easily burnt. Most of the arable land is devoted to the Potato culture, this district, with the surrounding neighbourhood, being the chief supply of the Bristol market in this article of food. Wheat is grown the first year, Barley next, then either seeds or Potatoes; if seeds, they are broken up for Potatoes, if Potatoes they are followed by Wheat. The Thornbury district is much crowded with Elm-trees, and the fields are generally small. Lime is used on this land generally once in a rotation, and is a most profitable outlay.—*M. S.*

Home Correspondence.

Drainage.—The castigation which my remarks in favour of one of our beneficial old practices have received, reminds me of an old sporting phrase—"It is a

dangerous maxim to bet odds against the favourite." Still, had they elicited a word of information in favour of the new systems, a good end might have been answered, and I might have been a winner. As only personal altercation is the result, I will say no more on the subject than may defend me from being misapprehended. I know tiles answer well in many situations, and do not object to their use; indeed I have drained with them myself. My objection extended only to the unscrupulous way of crying down practices which have been found beneficial, and which have the recommendation of experience, and taking up in their place new systems which are more expensive and backed chiefly by the opinions of theorists; tiles being decidedly more expensive than the Suffolk system of draining. My principal reasons given in favour of the draining which is chiefly pursued in my own county, are nearly as conclusive as the answer given by a celebrated breeder of the Southdown sheep, when asked why he preferred them to the Leicester:—"Because they answer my purpose better." I referred Mr. Girdwood to Mr. Pusey's Report on Draining, to show that Suffolk farmers are aware of the existence of the Royal Agricultural Society of England—which, by the bye, does not seem to extend its communications very far north; if it did, it might have spared my ludicrous ideas a little of the lash that has been applied to them. "To place tiles out of the way of any working whatever," they must be put little short of the bottom of an Artesian well, for I have a tile-drain on my farm well covered with stone, into which the worms have worked portions of clay through the apertures which let in the water. Your correspondent forgot, when addressing himself to my remarks, that it was down hill from the surface of the soil to the bottom of a drain on a perfectly level field. "Drains answering well for twenty years" only prove tiles equal to straw or stubble. I shall trouble you with only one more observation in answer to Mr. Girdwood. When I see practical men agree "as to how water gets into drains," and as to the uniform depth and width apart at which they are best made (which from your report of the late Yorkshire meeting does not appear to be the case at present), I will have no opinion of my own upon the subject; and I will give up my preference for transverse drains as soon as it appears practically clear that those parallel with the descent answer better. I can assure the learned Professor who has also, I find, noticed my remarks, and whose zeal for the advancement of science in Agriculture I duly appreciate, that it is only a fear of too much haste with too little speed, which has caused him to class me with the "halt of intellect" men who do not like "new-fangled schemes."—*Farmer and Valuer, Stowmarket.*

Great Produce.—Having seen in Mr. Lowe's account of the appearance of the crops for 1844, at the beginning of which he speaks of the Oxfordshire Wheat-ears of 80 grains in each, I inclose you one from this parish which you will find has 5-set kernels, and contains in all from 115 to 116 grains. This is not, by the bye, a solitary instance in this neighbourhood this season; many persons have 6 and some even 7-set kernels.—*A. Barfield.*

Thick Sowing.—Some years ago I had a very respectable foreman, so bigoted to thick sowing that if I did not watch him he would have his own way. To cure him, I laid him a new hat that I would beat him, planting (with a dibble) only 4 gallons of Wheat per acre, 12 in. × 6, and he should sow 25 gallons (his favourite quantity); at harvest he brought me the account, and I beat him 2 bushels per acre. Mine was hoed only twice: it ought to have been at least thrice, and deeper. This cured him.—*R. W. P.*

Failure of Turnips.—As so many persons are complaining about their Turnips, I think it fair to state what has happened to myself. I took a small farm last year which had been considerably impoverished by the former tenant, and resolved to try what could be done with it. Having worked and dressed the portion for Turnips very well, I drilled the seeds with great care, but after sowing twice I have only got a fair crop by considerable attention to transplanting in the places where they failed. Anxious, however, if possible to secure the white Turnip, I procured some of Lawes' superphosphate of lime, and on the manured ground I drilled the seed with 2 cwt. of the phosphate, mixed with ashes sifted through a fine wire riddle. I sowed two fields, and both have come up well without any failure at all. They were sown on a Saturday and appeared the following Thursday and Friday. They were speedily in the rough leaf, grew strong, bright, and healthy; nothing has touched them yet, and nothing appears to threaten them. I am so satisfied of the efficacy of this stimulant that henceforth I shall never sow Turnips of any kind without it. If the ground is not manured I suppose 2 cwt. would not be sufficient, but in my case it has been ample; and really 14*s.* an acre is a small expense to secure such an object.—*E. C.*

Allotments.—As you express the wish, in your Number of the 7th inst., that the subject of allotting portions of land to the working classes may be kept before the public, I will state, in accordance with that wish, that almost nine years since I apportioned several acres of land amongst a certain number of agricultural labourers, and that off one of those allotments which consisted (the portion which was sown with Wheat) of 63 perches, the occupier has just threshed out 3 qrs. 1 bush., including the gleaned Corn, being nearly at the rate of 8 qrs. (or, as we in this county term it, 16 combs) per acre. This man grows Wheat and Beans alternately, and feeds the pigs with the Beans generally, whilst in a green state. He pays me at the rate of 2*l.* per acre, free of all other charges. I may remark as an inducement to landed proprietors to adopt the allotment system, which I have long considered as tending greatly to add to the comfort, and also to improve the moral condition of the working classes, that I have never, in any instance amongst a considerable number of such occupiers, experienced any difficulty in obtaining the rent. I have omitted to state that the land is always highly manured for both crops, and cultivated solely by the spade.—*A Subscriber, Norfolk.*

Potato Failure.—A great misfortune, of its kind, has befallen me this year: my late Potato crop has completely failed. The tops were magnificent—finer in many parts than I ever saw—yet the crop was absolutely nothing, certainly not nearly enough to replace the seed. The land is light, on gravel, well manured with stable-dung, in many places with Potter's guano, and frequently watered with liquid manure, of human urine and soap-suds. The early Potatoes, called here Church's Seedlings, bore very fairly, but never before have I seen the like failure, with so splendid a promise from the stalks. Now what was the cause? The season? perhaps so; as I fear a like result is found by some of my neighbours who did not treat the growing crop as I did; or is the fault the system of manuring I adopted? I am very anxious to know, as this was my grand experiment in consequence of taking in your *Gazette*. My crop of Onions and Carrots have been excellent. Altogether I am quite baffled, and shall feel greatly obliged by your advice. I got tanks made on purpose for my garden, especially for the Potatoes, which I grow in great quantities.—*R.* [We do not know how to explain this; your fault must have been one of omission, if it be chargeable on you at all. The manures you applied cannot be blamed.]

Wheat.—The productiveness of Wheat has been frequently made a matter of newspaper astonishment, and I am almost ashamed to add my hundred-and-first wonder; but as none of the published "Extraordinary Crops" come up to anything approaching to the produce of the "Mummy Wheat," I may as well be heard in its just praises. The inclosed is a single root, the offspring of a single grain, and bearing 57 stems; there were 59, but 2 were broken off by accidental roughness before I thought the sample worthy of special preservation: one of the ears also accompanies it in this letter—an average one, neither the longest nor the shortest. You will perceive that it contains 48 grains—call it 45; then, 45 × 59 = 2655, or as many fold. The soil was new turfy soil, rather sandy, and entirely unmanured. My little crop was dibbled in grain by grain early in March, and cut early in August; height of straw above 5 feet. Many roots approached near to the one I send in size, but I believe it to be the largest; and the fact, as you perceive (if worth anything), is a matter of ocular demonstration. —*Martin F. Tupper, Brighton.*

Destruction of Turnip Crops.—The Cotswold farmer has moved my sympathy. I ascribe the evil to the effect of the season, on a soft ill-aired soil, impregnated with an excess (?) of azotised manure. I am ignorant of the character of the soil in question, but have seen similar effects in like conditions. I beg to recommend the trial of some of the cheapest disinfecters. One lot might be moderately dressed with newly slaked lime, another with chloride of lime, a third with common salt, a fourth with a mixture of salt and nitre, a fifth with a mixture of sulphur, nitre, and salt. The nitre and salt may be in equal weights, and 1 lb. of sulphur to 50 lbs. of the mixture. I would try these mixtures on small lots at first; give only about one cwt. of each dressing (except the lime) to the acre, and watch their effects. I could mention many others, but their price forbids field use. If anything better occur to any reader, state it, and let us soon hear whether that malady is giving way.—*G.*

Lucerne.—I have grown Lucerne this year for the first time. I have had a capital crop, and have cut it twice. It promises to be high enough and strong enough for another cut. Do you advise it?—*J. M.* [Yes.]

Potter's Guano.—Having seen (page 629) what is represented by your correspondent as an analysis of "Potter's Guano," I think it only right, in justice to myself, and out of consideration to those who may be led to make the manure from the formula given, expecting that it faithfully represents the composition of my guano, to state that this is far from being the case. I do not wish to impugn the accuracy of Mr. Mason, with whose name, however, as an analytical chemist I am unacquainted; but he has, in this instance, either got hold of a spurious article, or an error has arisen from some other cause. As it is not my intention as yet to make the public a present of the secret of my composition, nor to be entrapped by the putting forth of pretended analyses to declare what the correct analysis is, I shall content myself, in reference to Mr. Mason's, by saying, that those who follow it, although they will succeed in forming a very tolerable manure, will be sadly disappointed if they think they can substitute it for my guano. I will conclude by remarking, that although the analysis in question fails to declare truly what Potter's Guano *is*, yet it affords a negative evidence, at least, that it is not composed of chalk, sand, &c., as some have asserted, and that it is free from that cheap commodity WATER, which farmers, it appears, are willing to buy to the tune of some 25 to 35 per cent. in the foreign guano, paying for the same from 8*l.* to 10*l.* per ton, with a trifle more for carriage to their farms.—*W. H. Potter.*

Vetches and Italian Ryegrass.—In reference to a previous article on this subject, I beg to inform you that I sowed per acre, broadcast, 2 bushels of Vetches, ½ ditto of Italian Rye-grass, 14 lbs. of Cow-grass, and 2 bushels of Oats.—*W. Courtis, Swansea.* [Sown, we presume, not as a mixture, but successively on the same land.]

Societies.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the weekly meeting of the Council, on Thursday, September 5th, it was announced that his Royal Highness Prince Albert having been pleased to cause the sum of 500*l.* to be remitted, to be applied to the promotion of agricultural science in Ireland, this sum had been placed by Lord Eliot, at the disposal of the Royal Agricultural Improvement Society. A letter was also read from Lord Stanley, from the Colonial Office, accompanying a specimen of seeds of the Tussac Grass, lately imported from the Falkland Islands. The following are the terms of a premium of 5*l.*, given by Sir Harry Verney, Bart., to be competed for in the county of Galway, and to be decided at the next great national Cattle Show of the Society, to be held at Ballinasloe, for the province of Connaught, in the year 1845, viz.: "To the landholder in the county of Galway, who, being neither owner nor occupier of more than two statute acres of land, and recommended by a member of the Central Society, shall obtain from his holding the largest quantity of produce (not more than one-eighth being in Potatoes) during the year ensuing the meeting of the Royal Agricultural Improvement Society in Dublin." The secretary stated, that nearly all the premiums awarded at the late Cattle Show, amounting to near 700*l.*, had been paid off and discharged, with the exception of those which were subject to the conditions above mentioned; and that all the medals awarded on that occasion were now in preparation, and would be ready to be delivered to the parties, on application, in a few days.

SOCIETY FOR THE PROMOTION OF THE GROWTH OF FLAX IN IRELAND.

On Wednesday, 4th September, the monthly meeting of the Committee of this body was held at Belfast. The secretary read a Report of the quantity of Flax-seed imported into, and sown in Ireland, this season, prepared by a member of Committee, from the most authentic sources:—

FLAX-SEED IMPORTED INTO IRELAND, FOR SOWING, IN THE YEAR 1844.

Ports.	Riga brls.	Dutch hhds.	American hhds.	Total in hhds.
Belfast	20,123	2705	—	12,760
Derry and Portrush	23,083	900	200	12,630
Newry	—	—	—	3800
Dublin	—	—	—	2360
Limerick, Cork, and other ports ..	—	—	—	3500
Total ..	43,183	3605	200	40,196
Supposed quantity of home-saved seed sown				1200
				41,396
Deduct quantity on hands				500
Grand total of hhds. of Flax-seed sown this year ..				40,896
Total quantity sown in 1843				37,400
Increase over 1843				3496

From the above analysis of the importation this year, some interesting facts may be gathered. The quantity of American seed imported this season is only 200 hhds., while last year it was 4080 hhds. The decrease may be principally attributed to the strong manner in which the Society has cautioned the farmers against sowing American seed, which produces a branchy stem and coarse fibre. Home-saved seed has been sown extensively, and with success, many persons having very fine crops of Flax from it. It will be seen that Flax culture continues to increase in a steady progression. On the supposition that each hogshead would sow three statute acres, the quantity of land under the crop, in 1843 was 112,200 acres, and this year, 1844, is 122,688, an increase of 10,488 acres on the previous year. At the lowest average, each acre will produce 6 cwt. of clean scutched Flax; thus, the entire produce of Irish Flax last year was 36,465 tons, and this year, 39,611 tons—an increase of 3146 tons on the season's growth. The value of this 3146 tons, at 40*l.* per ton, which is a very low average, would amount to 125,840*l.* This large sum would otherwise have been paid to the Continental farmers, but is now retained in our own country. The superior elasticity and durability of Irish Flax over the Russian article is becoming daily more apparent, and the English spinners are more inclined to look to this country for their future supply. The committee resolved to allocate the sum of 50*l.*, in prizes for Flax and Flax-seed, at their Annual Show, in November this year, in addition to the 55*l.* already advertised as prizes, to purchasers of Flax on the foot.

FARMERS' CLUBS.

Wiltshire.—At the Annual Meeting of this Society, Mr. W. H. Browne, alluding to the condition of the agricultural labourers in Wiltshire, as compared with that of the labourers of some other counties, stated the average rate of wages in Wilts to be between 7*s.* and 8*s.* a week, and showed that, while there was a great redundancy of labourers, there were about 87,000 acres of uncultivated land in the county. He contended that if this land were, as it might be, brought into cultivation, the wages of the labourer would be raised, and his condition greatly improved; the poor-rates of the county, which now average 8*s.* in the pound—1*s.* above the average of England—would be diminished, and the welfare and happiness of all placed on a firmer basis. Mr. Browne referred, in proof of his assertion that the

waste lands he had alluded to were reclaimable, to the southern part of the county, where Mr. Brown, of Winterborne Stoke, and Mr. S. Mills, of Elston, had made the experiment, and had been amply repaid by the improved condition of their labourers, and the increased value of their property.—Mr. Mills corroborated the statement of Mr. Brown and observed:—As his name had been alluded to, as having converted some unprofitable soil to a good purpose, he would state that it had proved of great advantage to himself, as well as to the labourers throughout the county. He had of late adopted the system of stifle-burning, and this by mere chance. A man in his employ, who had come from a neighbourhood where it had been in operation, strongly recommended it. He consented to try it upon a piece of five acres; but before that was burned, he was so well satisfied of its advantages, that he ordered it to be tried on 80 acres. Those 80 acres had been valued by a highly respected surveyor at the annual rate of 1*s.* 6*d.* an acre. After the piece had been submitted to stifle-burning, crops of Turnips and Oats had been grown, that could not be exceeded on land for which 3*l.* an acre was given. —The process of stifle-burning is commenced by pulverising the land in the usual manner, namely, harrowing and rolling, so that the dead vegetable matter contained in the soil—as stubble, couch, or any kind of weeds—may be cleared of the mould as much as possible. When all this is sufficiently dry, it is collected together by men or boys with iron rakes into heaps at equal distances, the more readily to spread the ashes and burned soil. A small wad of dry straw is then added to each heap, and the earth is raked up over the heaps a few inches in thickness, before they are fired. No blaze or flame is suffered to escape, and not much smoke. The current of air being in some degree checked by the covering of earth, it becomes necessary to use from half a ton to a ton per acre of some sort of dry straw; that generally used is Wheat-straw. The last part of the process is spreading the heaps equally over the land. The whole is executed by men who travel from farm to farm for the purpose, at a cost of from 8*s.* to 14*s.* per acre.—*Bell's Weekly Messenger.*

Miscellaneous.

Sea-Weed as Manure.—The crops on the Isle of Thanet are superior to the crops grown in the inland counties; and, having travelled much by our railroads, I should say superior to any crops in the country. What is this superiority attributable to? There appears to be nothing very peculiar in the soil, and there is nothing peculiar in the rotation of their crops. I may be mistaken, but I attribute the superiority of the crops to the system of forming their dung-heaps, and the use of sea-weed as manure. The farmers on the island form their dung-heaps with alternate layers of sea-weed and farm-yard dung; and, after raising their heaps to the height of eight or ten feet, they cover the whole with a layer of eight or ten inches of sea sand. The sea-weed contains a portion of sea salt and fish, and on heating becomes very putrid and offensive. It may be difficult to analyse the compost of sea-weed and horse-dung, but it may be well to collect the liquor that oozes from the heaps, and have it analysed, when, I suspect, it will be found to correspond with guano in essentials. There is no doubt about its effect on the land, for the Wheat, in point of straw and ear, is so very superior that it cannot be improved in quality and quantity; and it only remains to be ascertained whether guano, or any other substance, in point of economy has any superiority. It is a mistaken notion to suppose that, by any contrivance, Wheat can be increased to any extent in a limited portion of land, or that more than a certain limited quantity of stalks of corn can be raised; every farmer knows that when stalks are too near together, they rot and decay. The great object to be sought is a healthy growth of straw, with a fine large ear, which shall yield a plentiful supply of good sound Corn; this result is attained on the island of Thanet. I was induced to inquire what was the cost of collecting the sea-weed on the island of Thanet, and was informed that the price paid at this season for it to the collectors of the weed was 6*d.* a cart-load in its wet state; this cart-load requires two strong horses to draw it, and may weigh considerably upwards of a ton; but when dry it may probably lose half of its weight, and much of its fertilising qualities. The farmers remove it in its wet state to their compost heaps, and do not lose the fertilising juices. I am induced to trouble you with these few observations, that our agriculturists may furnish employment to a very useful class of our subjects, who, in winter, have little or no employment.—I mean the boatmen of our sea-ports, who would be too happy to collect the sea-weed, and deliver it at the terminus of our railroads at probably 6*d.* per ton; for this is the price paid by the farmers to the agriculturists in the island of Thanet in the summer season, when other employment is obtainable; and, of course, in the winter, when there is little or no work going forward, and when the sea-weed is deposited in the greatest quantity, from the sea being ruffled and stormy, our boatmen would be too happy to obtain the employment on the same scale of wages. I am of opinion that the sea-weed might be pressed, by the aid of machinery, into a convenient compass, to render its transport by our railroads and by our ships not very expensive; and when our merchants are sending their ships to the South Seas for guano, they would enter into the speculation of conveying the sea-weed from our island sand-roads if the cost of the freight from our sea coast to the terminus of our railroads leading into the interior of our island would be realised.—*Correspondent of Mark Lane Express.*

Notices to Correspondents.

RURAL CHEMISTRY.—*By E. Solly, Esq., F.R.S. Experimental Chemist to the Horticultural Society of London, Honorary Member of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution,* may be had of all booksellers, price 4*s.* 6*d.*

ALPACA.—*H. S.*—We see no reason to doubt their success on Chalk Downs. Their usual price hitherto has been from 20*l.* to 30*l.* each. Their price in Peru is from 3 to 4 dollars; so that if they could be imported without loss by death, they might be sold with a fair profit at a comparatively cheap rate. We do not know where any are for sale.—*Subscriber.* —Apply to Messrs. M. & E. Dawson, 15, Islington Terrace, Liverpool.

ASPHALTE ROOFING.—*P.*—It is perfectly suited for roofing farm or any other buildings; no paint or other coating is required; it is laid on a boarded surface; and, except when that can be cheaply obtained, it is therefore expensive. About Alpacas, see above.

BELGIAN CARROTS.—*Yeoman.*—Harvest them just before their leaves get too rotten to enable you to pull the root up by. This will be when some of the lower ones have turned yellow. Keep them between two rows of flaked hurdles about 6 feet apart, and piled up in a ridged form, and thatched.

CHURNING.—*Anon.*—This operation is most successfully effected when the milk or cream is preserved at a temperature of about 75° Fahr.

DIBBLING.—*S. H. H.* had better dibble two seeds in each hole, lest one should fall a prey to birds, &c.

DRILLING MACHINE.—*J. B. Swete.*—Mr. Newberry's address is Hook Norton, Oxfordshire.

ELDER-BERRY WINE.—*Nemo.*—We must refer you to "The British Winemaker and Domestic Brewer," a small octavo volume, by W. H. Roberts: Whittaker & Co., London. With regard to our articles on Agricultural Mechanics, we must beg you to exercise a little patience: we can only say that we differ from you in opinion as to what has already appeared on that subject. Thanks for your suggestion as to the mode on which these papers should appear. We had already resolved in adopting, *in part*, some such plan.

FARM IMPLEMENTS.—*T. Hudson.*—The land alluded to is situated in South Sussex, on the Pevensey level, where rents are very high. The Vernon hoe is a narrow, almost dart-shaped tool with a sort of swan-neck, attached to a handle. It may be had, we presume, of implement-makers, or perhaps seedsmen.

LIQUID MANURE.—*A Farmer.*—Putrid urine requires about 1 lb. of sulphuric acid to fix the ammonia in 5 gallons of it.

LUCERNE.—*G. B. M.*—It will be all the better for the liming. It is best sown in rows, and perhaps dibbled; but it is too expensive work to transplant it.

MANURE.—*Melibœus.*—You had better mix it with double its quantity of vegetable mould; or, if you have it not, with a mixture of ordinary earth and charcoal dust, and you can apply it most beneficially perhaps to a green crop, Turnips, Potatoes, or Mangold Wurzel, under the last furrow which the land receives before the seed, at the rate of three cart-loads of the mixture per acre. It is not probable that the calcareous sand of which you send a specimen would benefit your clay; but as it is impossible to speak with certainty, you might try it on a piece of arable land, at the rate of one cubic yard on four perches of land.

POTATOE-HAULM.—*Three-year-old Subscriber.*—The removal of leaves such as cattle would relish as food would injure any plant that it is proposed to strip. You are mistaken in supposing that the young tubers might be exhausted in the effort to ripen the leaves; it is the agency of the leaf that ripens the tuber; and as long as they are green they are thus useful to the crop.

POTATO FAILURE.—*W. Ewing.*—Your report of the discussion is not sufficiently different from what has already appeared, to justify its publication. Will you favour us with your own views on the subject.

PROPER TIME TO REAP WHEAT.—*J. C. X.*—Thank you. A paper has been sent to the address you name.

SALT.—*Lapis.*—It can only be of use to the plants in solution; but you will find it cheaper to let it dissolve naturally, by sowing it in wet weather, than to apply it by means of the water-cart. Gas-water may be applied on meadow-land by means of the water-cart; apply 300 or 400 gallons per acre.

SEED-WHEAT.—*Improver.*—No charge is made.

SELF-SUPPORTING SCHOOLS.—*Subscriber.*—Mrs. D. Gilbert of Eastbourne, Sussex, has established several. We are not aware if there be any in the neighbourhood of Nottingham.

SPRING TARES.—*A Subscriber.*—It depends on the nature of the season. We think you may risk them.

TANK.—*Joe* has had a tank made with bricks upon arches, and made level with concrete, and about two months after it was quite dry he had one inch of Roman cement mixed with half washed road grit put over the bottom and side, and when that was set and hard he put the water in, and now it is leaking all over the bottom. How is he to *stop it?*

WILD DUCKS.—*Kent* asks if any of our correspondents can inform him whether wild ducks pair off, or what number of drakes are required to 20 ducks? Also whether the swan will destroy trout?

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, MONDAY, Sept. 16.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	3*s*	8*d*	to 4*s*	0	Best Downs & Half-breds	3*s*	8*d* to 4*s* 0
Best Short Horns	3	6	3	10	Best Long-wools	3	8 3 10
Second quality Beasts	3	10	3	4	Ewes and second quality	3	0 3 8
Calves	3	4	4	0	Lambs	3	8 4 4
Pigs	3	4	4	0			

Beasts, 3266; Sheep and Lambs, 23,960; Calves, 144; Pigs, 391.

We have to-day a large increase from last week in the supply of Beasts, and a consequent dulness in the trade, with a disposition to lower prices; although we cannot make alteration in our quotations for the best qualities, yet those prices are with difficulty obtained, and in some instances fail to be realised; several inferior Beasts remain unsold. Our supply of Mutton continues nearly the same; there is considerable activity in the trade for Longwools and the best Downs, but a remarkable dulness in the demand for Half-breds; the prices of the two former qualities are a shade better, the best Downs making rather over 4*s.*, and a few best selling Longwools a little more than 4*s.* 1*od.* per 8 lbs., but Half-breds scarcely reach the latter price. Good Lamb is in demand at late prices. Veal is about the same. Pork is rather lower.

FRIDAY, Sept. 20.

The supply of fresh Beasts is not very large to-day, and the prices of Monday are fully maintained—some of the choicest qualities realise a little more money. The trade for Mutton is very dull, but we cannot notice any alteration from Monday's quotations. The demand for Lamb is not quite so good; they make about the same as of late. There is a little more briskness in the Veal-trade, but the choicest make very little over 4*s.* per 8 lbs. Pork-trade is very heavy; it is difficult to make 4*s.* of neat Porkers.

Beasts, 767; Sheep and Lambs, 8160; Calves, 226; Pigs, 220.

4*l.* West Smithfield.

HOPS, FRIDAY, Sept. 20.

We have now a good supply of new Hops at Market, the demand for which is good. At Worcester Fair yesterday, about 2000 pockets were finished; the greater part sold from 4*l.* 4*s.* to 7*l.* 7*s.* The duty for this district is raised to 200*l.*, and for the Kingdom 130,000*l.* New Sussex, 4*l.* 10*s.* to 7*l.*; Weald of Kent, 7*l.* to 8*l.* 8*s.*; Mid. Kent and Farnhams, 8*l.* to 10*l.* 10*s.*

FARRINGDON & HAMPER, Hop-Factors.

WOOL.—BRITISH, FRIDAY, Sept. 20.

Our Wool Market remains unaltered from our last Report.

COVENT GARDEN, Sept. 21.—The market has been well supplied with both Fruit and Vegetables during the week, but trade has been far from brisk. Pine-apples are tolerably plentiful, and many handsome fruit are offered at from 3*s.* to 5*s.* per lb. The price of Grapes is rather on the decline; good Black Hamburghs are selling at from 1*s.* to 2*s.* 6*d.* per lb. There is no difference in the price of Melons since our last Report. Peaches and Nectarines still continue good, and are sufficient for the demand. Few Greengages are to be met with, and the supply of Dessert Plums is chiefly confined to Coe's Golden Drop, the price of which is from 6*d.* to 1*s.* per punnet. Damsons are still offered at the prices quoted in our last Report. Figs are becoming very scarce; they are selling at 2*s.* per dozen. Apples and Pears remain at nearly the same prices as last week. Filberts are scarce, and are therefore dearer; Oranges are also becoming very scarce; Lemons are tolerably well supplied, and a considerable quantity of foreign Walnuts are in the market. Vegetables have not altered much since our last report; Cauliflowers are offered at nearly the same prices as stated last week; Broccoli is good, and sufficient for the demand; and Cabbages and Coleworts are abundant; French Beans are rather on the rise; Onions are good and plentiful, and Carrots and Turnips are abundant; Tomatoes are rather cheaper; Lettuces, Endive, and other salading, are sufficient for the demand. Cut flowers chiefly consist of Gladiolus psittacinus, Combretum purpureum, Gardenia radicans, Heaths, Camellias, Amaryllises, China Asters, Pelargoniums, Fuchsias, Verbenas, Carnations, and Roses.

FRUITS.

Pine Apple, per lb., 2*s* to 5*s*		Morello Cherries, per hf.-sv., 1*s* 6*d* to 2*s* 6*d*

Spinach, per sieve, 1*s* 6*d* to 2*s*		Chilis, per 100, 2*s* 6*d* to 3*s*	
Leeks, per bun., 3*d* to 3*d*			

MARK-LANE, MONDAY, Sept. 16.

THE supply of Wheat from Essex this morning was moderate, that from Kent and Suffolk large; the first was taken off at the prices of last week, but that from the two latter counties barely supported those rates. Having a fair attendance of country buyers, Foreign Wheat met a slightly improved demand, but we are unable to raise our quotations, excepting for the finest qualities of new.—English Malting Barley must be written 1*s.* to 2*s.* per qr. cheaper; Foreign for grinding continues to be taken off at late terms.—New Beans sold 1*s.* below those which have hitherto appeared; old are unaltered in value.—Maple and Grey Peas have declined fully 1*s.* per qr.; White remain the same.—There was a fair show of Oats, including a few new Irish, the quality of which was moderate only, and great difficulty experienced in their disposal; old also sold slowly, but last week's prices were fully supported for Scotch.—Winter Tares are 6*d.* to 1*s.* per qr. lower.

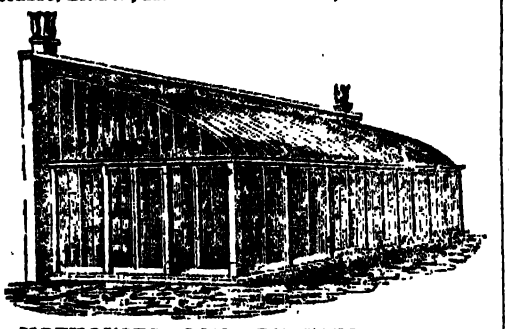
KINGSTON AND LAY.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.

Registered under 6 & 7 Vict., Cap. 65.

No. 189, FLEET STREET, LONDON.



BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.		Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
lb.	£ s.	s.	s. d.	s. d.	s. d.		
10	1 5	20	7 6	6 6	2 6	30 feet.	12 to 20
Ribbed Boiler.							
10	2 2	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12	3 15	20	13 6	7 6	3 6	80 to 125 feet.	40 to 65
14	5 10	35	17 6	8 6	4 6	150 to 250 feet.	65 to 100
18	5 5	42	25 0	8 6	5 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24	8 15	50	35 0	8 6	7 6	500 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

COTTAM AND HALLEN, ENGINEERS, IRONFOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

GUANO (GENUINE PERUVIAN & BOLIVIAN.

ON SALE, BY THE ONLY LEGAL IMPORTERS,

ANTONY GIBBS AND SONS, LONDON;

WM. J. MYERS AND CO., LIVERPOOL;

And by their Agents,

COTESWORTH, POWELL, AND PRYOR, LONDON;

GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.

47, Lime-street, Sept. 20, 1844.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 24 and 25, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to JAMES CLARK, 24, Billiter-street.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FOUNTAINE, 40, Upper Thames-street.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms, Cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Price-current, London, Sept. 19, 1844:—

Bones . .	p. ton	£4 10s.	0d
,, crushed,	£5. 10s. to	6	0 0

WM. NORTHCOTT, 13, Rood-lane, Fenchurch-street.

SEED-WHEAT. — Any one desirous of obtaining Seed-Wheat for use this autumn, may ascertain, by application to me, the particulars of the crops of two excellent varieties—Shirreff's Hopetoun, and Morton's Red-Straw White, which have been grown on

WHITFIELD FARM, THORNBURY, GLOUCESTERSHIRE, during the last 3 years. This year's crop is on sale at 8s. a bushel —JOHN MORTON, Whitfield.

SEED WHEAT.

J. D. PIPER, of Colne Engaine, Essex, (Member of the Royal Agricultural Society), has been four years raising two new Stocks of Wheat, viz., Piper's "Thick-set," and "Colne Whitechaff Red." At the last Southampton Meeting two sheaves of these Wheats were exhibited outside (notice not having been given in time for their admission inside), where they produced much excitement, and 5*l.* per ear was offered for them. Last year, in the same field, side by side, the Piper's Thick-set grew eight bushels and a half, and the Colne Whitechaff Red five bushels and a half more per acre than the most prolific Wheat grown in the neighbourhood. Last autumn J. D. P. measured a quarter of an acre off his field, and dibbled the Thick-set in rows a foot apart, and one bushel per acre; and though the plant was partially destroyed by the slug in the winter, and a good sprinkling of self-sown Potatoes were left to grow, still the yield was 14 bushels and a half, being equal to 14 sacks and 2 bushels per acre. One person this year grew 15 sacks and 2 bushels, another 14 sacks, and another 13 sacks per acre. One parcel weighed 64½ lbs. per bushel. This is, perhaps, the stiffest-strawed Wheat in England, and is adapted for strong or hollow bottom ground, and is not likely to get laid. J. D. P. will send to London, or to any place within ten miles of Colne, carriage free, and he will be glad to receive a post-office order, or reference to some house in London for the money, with the order for the Wheat. When it is all sold, J. D. P. promises to inform the Public, by an advertisement in this Paper; but if he should get any post-office orders after it is all sold, he will return them. The price is regulated according to the yield. Thick-set, 15*s.* per bushel; Colne Whitechaff Red, 9*s.* per bushel. Samples of the above, both threshed and in the straw, may be seen at our Office. N.B.—J. D. P. advertised in the two principal papers in Essex, where the above Wheat was growing, in order that Agriculturists might see it and judge for themselves of the quality and quantity.

WHEAT SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial, it being much more powerful, and free from adulteration, so justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

Testimonial to Brain's Guano Manure.—"5 A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation: (it is not adulterated, and can always be depended on, being of uniform composition.)—(Signed) JOHN MITCHELL and FREDERICK FIELD, Analytical Chemists, of the Royal Polytechnic Institution, London."

Also, BRAIN'S highly-concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1*s.* 9*d.* per quart bottle, with full directions for use, (enough for 80 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

TO AGRICULTURISTS.

CAMPBELL'S CORN STEEPS.—The Material for Wheat is on Sale by the undermentioned Agents, at 2*s.* 6*d.* per gallon.

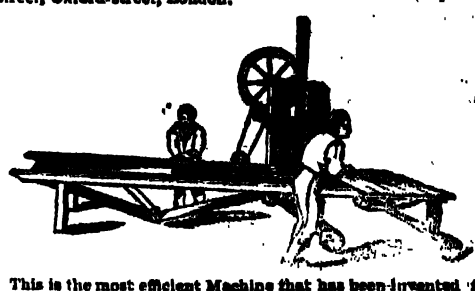
Notwithstanding the extreme drought of the last spring and summer, the results of the experiments, in very many instances, have been surprising, averaging a saving on seed, in the first instance, of 3*s.* per acre, and yielding a produce of 20 per cent. additional in straw, and 40 per cent. in grain. Had the season been more moist the result would have been at least double.

From Report of the Judges, Glasgow Cattle Show, Aug. 7, 1844.

"Among the remaining articles of the Exhibition (of Roots, Seeds, &c.), the Judges would direct attention to a series of specimens exhibited by Mr. James Campbell, of Dundee, consisting of various Grasses (they were Wheat, Barley, Naked Barley, and Oats), raised from Seed steeped in a Fertilising Liquid. These were contrasted with others which had not undergone the process, and were in all cases decidedly superior."

Agents:—Messrs. G. Gibbs, 26, Down-street, Piccadilly; Thos. Gibbs, corner of Half-moon-street, Piccadilly; and Edw. Purser, 40, New Bridge-street, London. W. E. Rendle, Plymouth Manure Company; J. Campbell, 5, Mersey-street, Liverpool; P. Bruce, Merchant, Hull; Crouch and Co., 66, Close, Newcastle-on-Tyne; W. F. Karkeek, Truro; John Mayer, High Offley, Staffordshire; George Griffith, Bewdley; J. B. Haden, Warminster; Phillips and Whittem, Coventry; John Towers, Maidenhead; Samuel Waldie, Carlisle; John Rodway, Carmarthen; James Black and Co., Aberdeen; W. Campbell, Merchant, Wick; Wm. Cuthbertson, Printer, Annan; J. and D. Campbell, Thurso; Maxwell Dick, Irvine; Dickson and Turnbull, Perth; Drysdale and Co., Glasgow; Drummond and Sons, Stirling; Wm. Dalrymple, Cupar Angus; John Dykes, Kilmarnock; James Haldane, Lauder; J. Bell, Dundee; Thos. Kennedy, Dumfries; A. Kennedy, Thornhill; P. Lawson and Son, Edinburgh; Wm. Law, Forfar; A. M'Farlane, Kinross; John Ogg, and Shield and Co., Arbroath; Geo. Robertson, jun., Kirkwall; John Rae, Elion; A. Simpson, Macduff; A. B. Telfer, Ayr; Wood and Co., Stonehaven.

IMPORTANT TO AGRICULTURISTS, &c.



ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5 A, Hawley-road, Kentish Town.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

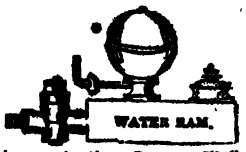
Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 20 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil-Cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch Street, London.

HATCHER'S BENNENDEN TILE-MACHINE, Manufactured and Sold only by COTTAM and HALLEN, Engineers, Agricultural Implement Makers, &c., 2, Winsley-street, Oxford-street, London.

This is the most efficient Machine that has been invented for the purpose of making Drain Tiles. Any shaped Tile can be made by merely changing the die, which can be done in a few minutes. It requires but few hands, viz., one man and three boys. With this amount of labour, the product of a day of 10 hours is as follows, viz.:—

1 inch diameter of Tile,	11,000	12 inches diameter of Tile,	5,000
1½ ,, ,,	8,000	24 ,, ,,	2,200



The Machine is movable down the drying-stands, so that it requires no extra boys to carry the Tiles; nor does shelves be required in drying. It has been in full operation for upwards of four months at Hempstead Park, near Craybrook, Kent. No charge made for Patent dues or licence. The purchase of the Machine includes free use of it.

J. R. AND A. RANSOME, Ipswich, have published a Descriptive Catalogue, with Cuts, of their AGRICULTURAL IMPLEMENTS and MACHINES, which may be had by post, the order being accompanied by six penny stamps.

70, STRAND, LONDON.

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c.

F. ROE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1*d.* per foot, super. A discount to the trade. THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S  ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

TERRA COTTA FIGURES, VASES, FOUNTAINS, &c. Manufactured by DOULTON and WATTS, LAMBETH POTTERY, High-street, Lambeth, London.

D. and W., from their experience as Potters, have made considerable improvements in the manufacture of Terra Cotta, the superiority of which over Artificial Stone or Cement is well known. It is subjected to a high degree of fire, which renders it imperishable, and gives it a sharpness and surface which no changes of temperature can impair.

D. and W. are enabled to offer the Terra Cotta at a considerable reduction in price; and Drawings and Designs will be forwarded Gratis, on application.—Architectural work executed.

THE WORKS OF G. P. R. JAMES, ESQ.

On the 1st October will be published the second volume of the NEW and ILLUSTRATED EDITION of Mr. JAMES'S WORKS, comprising the whole of the celebrated Historical Narrative entitled

MARY OF BURGUNDY.

This new and attractive series commenced on the 1st July with "THE GIPSY" (of which a second edition has already been required). The future Volumes will be published quarterly, each containing a complete W[illegible] (originally published in three volumes at 31s. 6d.) The whole of this Edition has been carefully Revised by the Author, and will be got up in that superior style and agreeable size of type, &c., which render it fit for any age and for every library.

Published by SMITH, ELDER, and Co., London, and may be had of every Bookseller in the Kingdom.

THE HORTICULTURAL MAGAZINE.—On the 1st October will be published, price 1s., the introductory Number of the new Periodical. Orders received by all Booksellers. Contents.—Science of Gardening; Advantage of a Garden; Annals of Horticulture; Manure, and its Application; New Flowers; Fruits and Vegetables; Lands and Gardening; Planting; Improving Estate; Cutting; Acclimatising; Irrigation; Wonderful Vegetable Productions; the various Classes of Plants; Hybridising Plants and Vegetables; Designs for Conservatories, Gardening for Manufacturing Towns; Construction of Fountains; Substitute for Grass; Lawns and Shrubberies; Fruit Gardens and Orchards; Geology, Soils, Notes to Correspondents, &c.

T. HOLDITCH, Publisher, 144, Strand, London.

NEW WORK ON AGRICULTURAL CHEMISTRY

This Day is Published in One Volume post 8vo,

LECTURES TO FARMERS ON AGRICULTURAL CHEMISTRY. By ALEXANDER PETZHOLDT.

Printed for TAYLOR AND WALTON, 28, Upper Gower Street.

NEW WORK BY PROFESSOR LIEBIG

This Day is Published in foap 8vo,

FAMILIAR LETTERS ON CHEMISTRY.—*Second Series.*—The PHILOSOPHICAL PRINCIPLES AND GENERAL LAWS OF THE SCIENCE. By JUSTUS LIEBIG, M.D., Ph.D., F.R.S., Professor of Chemistry in the University of Giessen. Edited by JOHN GARDNER, M.D., Member of the Chemical Society.

Printed for TAYLOR AND WALTON, 28, Upper Gower Street.

COMPLETION OF THE BOOK OF THE FARM

Next week will be published price 8s. Parts XX. and XXI. completing the Work, of

THE BOOK OF THE FARM,

By HENRY STEPHENS, F.R.S.E.

ILLUSTRATED WITH WOOD ENGRAVINGS

At same time will be published,

The SECOND and THIRD Volumes, handsomely bound in cloth.

WILLIAM BLACKWOOD & SONS, Edinburgh and London.

JOHNSON'S GARDENERS' ALMANACK FOR 1845, will be published by the Stationers' Company in November. All Advertisements must be sent before November 1.

N.B. The Eighth Edition of the Almanack for 1844 having been entirely sold off, a Ninth has been printed for the supply of those who, beginning to take it in 1845, may be desirous of having the work from its commencement, but as it cannot again be reprinted, the public are warned that as the number is very limited the application for it should be immediate.

Just published, the Thirteenth Edition, price 2s 6d, free by post, 3s 6d,

THE SILENT FRIEND ON NERVOUS DEBILITY, CONSTITUTIONAL WEAKNESS, &c. By R. and L. PERRY and Co., Surgeons, London. Published by the Authors, and sold at their residence; also by Strange, 21, Paternoster row; Noble, 169, Chancery lane; Lockyer, 1, Milton-lane, Strand; Ward, 166, Strand (opposite Exeter Hall); Gordon 146 Leadenhall-st; Purkiss, Compton-st, Soho; Wilson, 118, Oxford-st (two doors from Argyll-st), London. The Cordial Balm of Syrian is a stimulant and renovator in all Spasmodic complaints Nervous Debility, Indigestion, Asthma, and Consumption, are gradually and imperceptibly removed by its use, and the whole system restored to a healthy state of organisation. Sold in bottles, price 11s and 33s. PERRY'S Purifying Specific Pills have long been used as the most certain remedy for Scorbutic Complaints of every description, Eruptions of the Skin Pimples on the Face, and other disagreeable affections the result of an impure state of the blood. These Pills are perfectly free from mercury and other deleterious drugs, and may be taken with safety without interference with or loss of time from business, and can be relied upon in every instance. Sold in boxes, at 2s 9d, 4s 6d, and 11s, by all Medicine Venders.

Messrs PERRY and Co may be consulted daily at their residence, 19 Berners street, Oxford street, from 11 till 2, and from 5 till 8. On Sunday, from 10 till 12.

HORTICULTURAL SOCIETY OF LONDON

This Day is Published, price 3s 6d to Fellows of the Society, and 5s to others

A CATALOGUE OF THE FRUITS Cultivated in the Garden of the HORTICULTURAL SOCIETY OF LONDON. Third Edition. Sold by LONGMAN & Co. Paternoster row; J. HATCHARD, Piccadilly; RIDGWAY Piccadilly; RIVINGTONS, Waterloo place, and by the principal Booksellers in all parts of the Empire.

A few copies of the Second Edition of this Catalogue may be had at the reduced price of 1s 6d each.

Price Sixpence, free by post.

ADVERTISEMENTS IN THE MONTHLY JOURNAL OF MEDICAL SCIENCE, Edited by Dr. CORMACK. Few Periodicals present such advantages to the Advertisers of Medical and Scientific Publications, Works in General Literature, Medical Practices, Chemical Products, Pharmaceutical Preparations, the Prospectuses of Life Insurance Societies, &c. The circulation is large, and has from its commencement gone on steadily increasing in Great Britain, Ireland, India, America, and the Continent of Europe. It is taken in by many General News rooms, by almost all of the Reading Clubs and Medical Societies in Town, and by a very large proportion of Country Practitioners, in England, Scotland, and Ireland, to whom, from its cheapness and comprehensive character, it is specially adapted. Advertisements inserted in this Journal must be seen by many thousands of the most select class of readers.

*** For the SCALE OF CHARGES, and all other particulars, reference may be made to Mr. Churchill, Princes-street, Soho, London; Messrs. Maclachlan, Stewart, and Co., South bridge, Mr. Jack, Niddry street, Messrs. Harthill and Son, Waterloo-place, and Mr. Seton, Head of the Mound, Edinburgh; Messrs. Fannin and Co., Dublin, most News Agents in Great Britain; and Messrs. Fortin, Masson, et Cie, Paris.

On the 1st of October, in demy 8vo, price 6s,

THE NEW QUARTERLY REVIEW (No. 2); and HOME, FOREIGN, and COLONIAL JOURNAL, being the 8th Number of the FOREIGN and COLONIAL QUARTERLY REVIEW.

London: SMITH, ELDER, and Co., 65, Cornhill.

LEA AND PERRINS'S WORCESTERSHIRE SAUCE. Prepared from the Recipe of a Nobleman in the County.

"*Great Western Steam ship, June 6*, 1844.—The cabin of the Great Western has been regularly supplied with LEA & PERRINS'S Worcestershire Sauce, which is adapted for every variety of dish, from turtle to beef, from salmon to steaks, to all of which it gives a famous relish. I have great pleasure in recommending this excellent sauce to Captains and Passengers for its capital flavour, and as the best accompaniment of its kind for a voyage. (Signed) JAMES HOSKEN."

"One of the most piquant inventions of this luxurious and epicurean age is Lea and Perrins's Worcestershire Sauce, adapted to fish, flesh, fowl, and soup; giving a zest far superior to the long-established favourites; more wholesome and of less cost."—*Naval and Military Gazette*, April 9, 1843.

Sold Wholesale by the Proprietors, Messrs. LEA and PERRINS, Worcester; Messrs. BARCLAY and SON, Farringdon-street; and the principal Oil and Italian Warehousemen in London; and Retail by the usual venders of Sauces.

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers as follow:—Cottage Pattern—1 Cover of 20 inches, 3l. 12s; 1 do. of 18 inches, 2l 8s; 2 do of 14 inches, 4l. 8s.; the set of 4, complete, 11l. 12s. ONLY. Double Dome Pattern—1 Cover of 20 in., 3l. 16s, 1 do. of 18 inches, 3l 12s.; 2 do. of 14 inches, 5l. 5s.; the set of 4, complete, 14l ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7s. 3d. per oz.; Queen's Pattern, 7s 4d per oz. GARDENERS' CHRONICLE.—To be Sold, a bargain, the three First Volumes of the GARDENERS' CHRONICLE, complete and in good order, unbound, for 3l 10s. Apply, if by letter pre-paid, to Mr. JENNINGS, Florist, South Lambeth-road, Vauxhall.

SUPERB DOUBLE HOLLYHOCKS.

WILLIAM RAY begs to announce that he is now prepared to send out his collection of the above splendid and showy plants, of all the various shades of colour, from black, or dark, to white. As his stock is large, he is enabled to supply them upon very moderate terms, viz., 42s. per 100.

N.B.—As this plant is becoming popular as a show flower, W. M. has a few very select varieties, by name and colour, at 20s. per dozen, which he has selected for the purpose of exhibiting. Also Seed selected from finest double flowers, in packets at 2s. 6d. and 5s. each, post-free. The above may also be had by order of the principal Seedsmen in London, and of Mr. WILKINSON, Market-place, Manchester. A remittance or reference from unknown correspondents.

Hope Nursery, Bedale, Sept. 25.

MR. HOYLE'S NEW SEEDLING GERANIUMS.

MR. MILLER begs to call attention to the Advertisement of these splendid flowers in last week's *Chronicle*, and also states that printed Lists, giving full descriptions, are now ready, and may be had Gratis.

Providence Nursery, Ramsgate, Sept. 26.

NEW ALONA CÆLESTIS.

J. J. BEST begs to inform the Trade, the Public, and his Friends in general, that, having taken (as successor of Mr. Henry Hamond, who is retiring from business) the Abbey Nursery, Reading, Berkshire, he intends, if possible, sending out (middle of October) established plants, in 60-pots, of that Gem of Greenhouse-plants — ALONA CÆLESTIS. The above is figured in the "Botanical Register" for September, "Paxton's Magazine," "Plant's Florist's Journal," and "Harrison's Cabinet" for October. ALONA CÆLESTIS is a half-hardy evergreen greenhouse-shrub, from Chili; flowers, sky-blue; the size and shape of a Petunia; a good erect habit, and freedom of growth; has proved a perpetual bloomer since May last, and likely to continue much longer. Price One Guinea per plant; the usual discount to the Trade, when two plants are taken at once. Early orders are respectfully requested, as the Stock is very limited; one-third of the value will be taken in Stock from Trade orders.—Direct to J. J. BEST, Abbey Nursery, Reading, Berks, September 25.

SUPERB SHOWY SEEDLING CINERARIAS, for this autumn and winter flowering.

Dwarf, bushy plants, well trussed for bloom, in 32-sized pots, 12s. per dozen.

Do. do. in 48-sized pots, 9s. per dozen.

The above can be confidently recommended as being saved from the very choicest and most superb kinds, comprising every shade of beautiful light and dark-blue tints, and admirably adapted for the furnishing of the greenhouse or drawing-room, throughout the autumn and winter months. Seed selected from the same, 2s. 6d. per packet.

THUNBERGIA CERYSOPS.—Plants of this beautiful Creeper, rich purple flower, with golden eye, 7s. 6d. each.

M. B. has a large stock of the following STRAWBERRIES:—

Myatt's British Queen	6s. per 100.
Do. Eliza	6s. "
Emperor, variety from Keen's Seedling	3s. "
Green-flesh Pine, small fruit, fine flavour	3s. "
Elton Pine	2s. 6d. "
Keen's Seedling	2s. 6d. "

Applications, including post-office orders, will be immediately and carefully executed, addressed to MICHAEL BREWER, Sen., London-road Nursery, Cambridge.

HYACINTHS, &c.

JOHN THATCHER AND SON, SEEDSMEN, &c., 32, High-street, Islington, respectfully inform the Nobility, Gentry, and the Public generally, that they have imported a large and choice collection of Dutch Flower-roots, consisting of Hyacinths, Narcissus, Jonquils, Tulips, Anemones, Ranunculuses, Crocuses, &c., Catalogues of which will be delivered post-free on application. Also that they are manufacturers of all kinds of Flushing and Bowling Nets. Hays for Rabbits, Nets for Nets, &c. &c.

THE NEW SUPERB SEEDLING PICOTEE, "BURROUGHES'S DUKE OF NEWCASTLE."

YOUELL & CO. have much pleasure in announcing they will send out for the first time the above splendid light-edged purple Picotee, raised by the Rev. J. Burroughes. It is guaranteed to surpass any Purple Picotee that has yet been raised. Without commenting further upon its superiority, Y. and Co. beg to refer to a report in a late No. of the *Gardeners' Chronicle*, as follows:—

"The *Duke of Newcastle* is a flower of first-rate properties, it is a light-edged purple; the petals are large, and of good form and substance; even on the edge; the colour unbroken; the pod good, and with less disposition to bar than is common." It obtained the first prize, as the best seedling, at the Norfolk and Norwich Horticultural Exhibition. Price 21s per pair. The stock being limited, to prevent disappointment early orders are respectfully requested. Y. & Co. are also enabled to supply the following superb Picotees, raised by the same gentleman, all possessing first rate properties, and having been exhibited and obtained first class prizes at several of the metropolitan Exhibitions of the present year. They are as follows —

Burroughes's Mrs. Benyon, Red Picotee	7s	6d.
" Lady Alice Peel, Rose Picotee	7	6
" Miss Jane, Purple Picotee	7	6
" Mrs. Bevan, Red Picotee	7	6
" Enchantress, Scarlet Picotee	5	0

CARNATIONS AND PICOTEES.

Y. and Co.'s collection of this beautiful tribe of flowers will be found the most extensive and select in Europe, comprising every known variety of merit. The plants are remarkably strong and healthy, and ready for sending out to any part of the United Kingdom and the Continent at the following prices

12 pairs extra fine and very superior first class Show £ s. d.

Flowers				2	10 0
25	ditto	ditto	ditto	5	0 0
12	ditto	ditto	Show Flowers	1	10 0
25	ditto	ditto	ditto	3	0 0
12 pairs of Extra fine Show Pinks				0	12 0
25	ditto	ditto	ditto	1	1 0

The selection being left to Y. and Co.

*** For Particulars of their importation of the finest HYACINTHS, &c., direct from Haarlem, see Advertisement of last week.

Great Yarmouth Nursery, Sept 27, 1844.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Acre-lane, Brixton, Surrey, has prepared for the growers of these splendid flowers a Catalogue, enabling them to judge of their qualities, with the prices annexed, which may be had at the Nursery, and of Messrs WARNER & WARNER, Cornhill, London, after the 7th September.

DOUBLE ROMAN and PAPER WHITE NARCISSUS, 4s. per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. CORBETT'S, late Mr. BARNON'S, Italian and Foreign Warehouse, 19, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

WOODLANDS NURSERY, Maresfield, near Uckfield, Sussex.

WM. WOOD AND SON, have an immense stock of the following good and approved kinds of STRAWBERRIES, strong plants of which are now ready for immediate transit —Myatt's British Queen, 5s. per 100, Eliza, 5s, Elton Pine, 8s; Princess Royal, fine, 7s. 6d.; Princess Alice Maud, 30s., Deptford Pine, 21s., Keen's Seedling, 3s. A remittance or reference is respectfully solicited from unknown correspondents.

Catalogues of the general Nursery Stock, and the new Rose List, are now ready, and may be had Gratis on application.

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONES, GERANIUMS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment FLORIST TO HER MAJESTY, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above Flowers, which, from the success he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the highly-flattering remarks on his Exhibitions of Tulips and Lilium lancifolium this season, in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their parterres with these beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for parterres, as, besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much wanted. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

SPLENDID NEW PLANTS.

JAMES CUTHILL begs most respectfully to announce that he has now ready to send out strong, healthy plants of the following:—Lisianthus Russellianus, 2s. 6d. to 5s. each; L. nigrescens, 5s. to 10s.; L. longifolius, 5s. to 10s.; L. corymbosus, 10s each; L. glaucifolius seed, at 2s. 6d. per packet. J. C. has a splendid Yellow Lisianthus which will be sent out next year. A Treatise will accompany each order on the best method of growing the Lisianthus. Fine roots of the Prince of Denmark Scarlet Clove-scented Carnation, an excellent forcer, 12s. per doz.; Petunia grandiflora (Van Houtte), a fine pencilled lilac, 1s. each; also Fleming's Trentham Cabul Melon, which gained several prizes at Regent-street—the best-flavoured and most extraordinary bearer; three lights produced 90 lbs. first crop—40 the second; and is now bearing the third; 2s. 6d. per packet. Latter's Victory of England Cucumber, 2s. 6d. to 5s. each; Cuthill's early improved Black Spine, very handsome, 2s. 6d. per packet, or the three for 6s. The trade supplied by the ounce of the above Cucumbers, by sending a money order on the Camberwell Post-office.—Letters directed to J. CUTHILL, Florist, Denmark-hill, Camberwell, London, will be immediately attended to.

N.B. The Lisianthus nigrescens can be seen in bloom 7 feet high, with upwards of 1000 blooms upon it, and will continue in flower till Christmas.

RAY SOCIETY, instituted 2d February, 1844.—This Society has been formed upon the principle of the Parker, Camden, Sydenham, and other Societies, for the purpose of securing to those attached to the study of Natural History, such Works on the various branches of Zoology and Botany as could not be obtained by other means; and will consist of original works, of new editions of works of established merit; of rare tracts and MSS; and of translations and reprints of foreign works. Every subscriber of One Guinea annually will be considered a member of the Society, and will be entitled to a copy of every work published by the Society. The Council have great pleasure in stating that the number of Members already exceeds 300, and beg to call the attention of their friends to the necessity of sending in their names as early as possible, in order that they may be enabled to determine the number of copies of their works which they ought to print. The Council hope to publish two volumes before Christmas, the first of which will consist of translations from the German and Italian, of Reports on the progress of Zoology and Botany during the last few years.

Communications on the business of the Society are requested to be addressed to the Secretaries, Dr. George Johnston, Berwick-upon-Tweed, and Dr. Lankester, Golden-square, London. Subscriptions to be sent, by post-office order or check, to the Treasurer, J. S. Bowerbank, Esq., 45, Park-street, Islington.

GEORGE JOHNSTONE, M.D.
EDWIN LANKESTER, M.D. } Secretaries.

J. T. WILLMER, King's Road, Chelsea, by Appointment Florist to Her Majesty, begs to inform his Friends and the Public that his Carnations and Picotees are now ready for sending out, catalogues of which may be had on prepaid application containing a postage stamp.

SPLENDID NEW HEAVY-EDGED PURPLE PICOTEE, WOOD'S "PRINCESS ALICE"

JOHN WOOD begs to announce that the stock of this superb flower is now ready for sale at 15s. per pair, postage included. It has gained the following prizes:—At Cambridge Florists' Show, 1843, it was the 1st seedling, and the 1st heavy edged purple; at the same Show, in 1844, it took the premium prize, beating all the Picotees exhibited. At Huntingdon, 1843, it was 1st seedling and 1st purple Picotee; at the same place, 1844, it was 1st, 2d, 3d, and 4th, excluding every other flower. At Peterborough, 1843, it was the 1st seedling, took 1st pair of purple, and was in the best stand of six Picotees; in 1844, at the same Show, it took the 1st pair, and was again in the 1st stand of six.

J. W flatters himself that this statement precludes the necessity of farther comment. Plants of the above may also be had of HUNT and M'MULLEN, 6, Leadenhall-street.

J. W. has a few pairs of that splendid Pink, Garratt's "Queen of Roses," for sale, at 7s. 6d. per pair; his Catalogue of Carnations, Picotees, &c., may also be had on prepaid application; and those about to commence growing, he will supply as follows:—M left to his selection.

CARNATIONS AND PICOTEES.

DICKSONS and Co will be glad to communicate with Noblemen or Gentlemen requiring Gardeners, Farm Stewards, Foresters, &c, as they have on their list men of very superior character and ability —1, Waterloo place, Edinburgh, Sept 1844

NEW PLANTS

MESSRS. VEITCH AND SON have now ready for sending out the two undermentioned beautiful New Plants, viz —

HINDSIA VIOLACEA Strong plants at 5s It is figured by Dr LINDLEY in the "Botanical Register" for August last, who there says—"The Hindsia violacea is one of the finest things obtained from South Brazil It has been imported by Messrs Veitch and Son, of Exeter, who received for it the Large Silver Medal at the Horticultural Society's Garden Exhibition in May last It will doubtless prove a very easily cultivated Greenhouse Plant, and is certainly unsurpassed in beauty by blue flowering shrubs"

CATTLEYA PUTUMEA. Strong plants at 42s This plant was exhibited at Chiswick, in May, under the name of Cattleya maxima species, and received the Knightian Medal. See Report in *Gardeners' Chronicle* for May 25. It is figured in "Paxton's Magazine" for July last

Messrs V and Son have also to offer the following fine plants, viz —

Achimenes picta	Gardenia Sherbourneia
Allemanda grandiflora	" tetraptera
Barbacenia aquatica Veitchii	Gesneria polyantha
Clerodendron laxiflorum	Gloxinia Cartlettii
" splendens	Hoya imperialis
Cyrtoceras reflexa	" longipulcherrima
Echites atropurpurea	Luculia gratissima
" hirsuta	Passiflora racemosa
" splendens	Pentas carnea
Gardenia Radicans	Thunbergia chrysops &c &c

N B — Messrs V and Son's General Catalogue can be had on application — Exeter, Sept. 27, 1844

ROSES

A PAUL AND SON respectfully announce that their Annual Descriptive ROSE CATALOGUE will be ready for circulation in a few days, and may be obtained from the Nurseries post free, upon application inclosing two postage stamps Their stock is very large, and having been grown on new ground the plants are more than usually robust and healthy All the really valuable new Roses are in their collection

TO NOBLEMEN and GENTLEMEN PLANTING —A PAUL and SON would also call attention to their Fruit and Forest Trees Ornamental Trees, Shrubs, Evergreens, &c. &c, which are growing on upwards of 25 acres of ground, and are on sale upon the most reasonable terms. The soil is a stiff loam, from which they remove in perfect safety, having abundance of fibrous roots and the earth adhering thereto. The proximity of the Nurseries to the Metropolis, and the advantageous terms of sale, recommend them especially to gentlemen planting.

Nurseries, Cheshunt Herts, 12 miles from London, near the Waltham Cross Station on the Cambridge Line of the Eastern Counties Railway

EARLIEST STRAWBERRY in CULTIVATION. —Strong Plants of the "PRINCESS ALICE MAUDE" STRAWBERRY, which has proved itself to be the earliest grown in this country, are now ready to be sent out at 20s. per 100. As an Early Strawberry, it has taken the First Prize at all the Horticultural Exhibitions in the early part of the season Also Plants of the "British Queen," "Deptford Pine," "Prince Albert," and all the leading kinds To be had of Messrs. WARREN & WARREN, Seedsmen, 28, Cornhill, London.

CAMELLIA JAPONICA.

ROBERT LAWSON, Esq., of Tiverton, intends disposing of his stock of Camellias, which he has collected at much expense, and successfully cultivated for many years. They are in the highest state of health, and most abundantly set with blooming buds Mr L. disposes of them solely in consequence of their having become too large for his conservatory They are as follow —

				£	s.	d.
Reticulata,	from 7 to 8 feet in height, a very fine specimen, quite healthy and green			10	10	0
Imbricata,	from 7 to 8 feet in height,		do.	8	8	0
"	" 3 to 4	"		1	10	0

The Prices affixed are for the separate plants, of which not less than 8 can be taken together If the whole are taken in one lot a considerable reduction will be made Mr Lawson will be happy to show them, or give any further particulars that may be required —Tiverton, Sept 27th, 1844

NEW SEEDLING AZALEAS AND CINERARIAS

WM. IVERY, FLORIST, &c, Peckham, near London, begs to inform his Friends and the Public that he is ready to supply the undernamed Plants, which he can with confidence recommend

AZALEA ATHERITIA FORMOSA, bright red, 21s to 31s 6d each "A Certificate of Merit was awarded to Mr Jas Ivery, of Bethworth, having large flowers, clean and bright in colour, and expanding freely"—DR LINDLEY in *Gard Chron*, *May 25*

AZALEA COCCINEA SUPERBA, bright scarlet, good shape, and free bloomer, 15s each, Azalea delicata, bright pink, good shape, and abundant bloomer, 15s each

CINERARIAS —Beauty of Wonham, very large white beautiful eye and dwarf habit, 5s, tricolor, white and pink, brown eye, compact flower, 5s, Nosegay, purplish blue, good petal, and noble truss, 5s, Washington, very large crimson, good petal 5s, Captivation, white ground, with beautiful maxarine purple tips, gained first Prize at the West Kent Junt Exhibition, 7s, Criterion, mazarine blue, beautiful white centre, gained first Prize at Dorking May Exhibition, 7s 6d, Red Rover, bright crimson, beautiful prolific bloomer, 5s, Fanny Elsler, white crimson tips, prolific bloomer, 5s, Pickwick, bright purple large flower, and fine shape, 1s 6d; Compacta, small, white, and beautiful round flower, 5s

The whole set of Seedling Cinerarias, *21 5s*

The following CINERARIAS can be recommended as good — Ivery's Beauty of Syston, bronzy purplish blue, fine winter flowering var, 2s 6d, Emperor 1s, Pride of Peckham, 2s 6d Regulata, 2s. Delicata, 1s 6d, Regina Victoria, 2s 6d; Triumph, 2s Rival King, 1s, Imperial Blue, 1s, Royal Blue, 1s, Ivryana, 1s 6d, Princess Royal 1s 6d; Queen Victoria, 1s 6d, Exquisite, 2s 6d, Wee Pet, 1s 6d Hendersonii Azurea, 1s 6d Pilot, 1s 6d Unique 1s 6d Magnet, 1s 6d; Prince of Oldenburgh, 1s 6d; Bombre Agreeable, 2s 6d, Eclipse, 1s 6d, No 7, 1s 6d, Enchantress, 1s 6d, Compact Blue, 1s 6d; Bell's Decora 1s 6d Good's Compacta, 1s 6d; Gaines's True Blue, 1s 6d; Prince Albert, 1s 6d, May's Queen of May, 2s 6d Youngii, 1s 6d Good varieties from 9s to 12s per doz Fine Cineraria Seed, 2s 6d to 5s per packet

Fine PETUNIA, noticed in "Calendar of Operations," *Gard Chron*, Sept 14 Ivery's Pet, 1s 6d to 2s 6d Magna Charta, 1s 6d to 2s 6d; Reliance, 1s 6d to 2s 6d, Ovid, 1s 6d Prince Albert, 1s 6d to 2s 6d, Scottish Beauty, 1s 6d, Enchantress, 1s

JOSEPH FRYER begs respectfully to inform his Friends and the Public, that he will have ready in a few days Catalogues containing his choice and extensive Collection of PANSIES VERBENAS, FUCHSIAS PETUNIAS, CARNATIONS, PICOTEES, PINKS, Greenhouse and Herbaceous Plants, &c &c, likewise a separate Catalogue of Dutch Bulbous Roots, which will be forwarded on application J F begs to observe that his plants are in excellent health, true to name and at very low prices —Clarendon Nursery, Camberwell, London, Sept 27

PARKSTONE NURSERY, NEAR POOLE

J. PIPER'S NEW SEEDLING FUCHSIA, PICTA —This flower has been submitted to Professor LINDLEY for inspection, and has been pronounced by him to be a good flower It is large in size, the tube and sepals of a delicate but bright pink, the latter tipped with green, the corolla of a rich rosy crimson, slightly tinged with lilac The flower is well developed, and of admirable form and substance It is altogether a most desirable variety, and ought to be in the collection of every cultivator of this beautiful tribe

LARGE DOUBLE WHITE ROCKETS

S. AND J DILLISTONE have a fine stock of the above, which will be sold reasonable Also some strong SEEDLING CINERARIAS, from the choicest named ones of last season Prices &c upon application —Nurseries, Sturmere, Essex, near Haverhill

CRAIG'S PROLIFIC FORCING CUCUMBER.—This unrivalled variety for Early Forcing in Pots, Boxes, or Frames, is now ready for distribution, and may be had per post at 2s 6d per packet of six seeds. For supplying a family this variety is unequalled, being a cross between the Sion House Frame and Smyrna, and combines the good properties of both its parents Apply to Mr Edwards, Seedsman, Bridge-street, Hull to Mr Geo Charlwood, Seedsman, Covent-garden, to Messrs Flanagan and Son, Mansion-house-square, London, or to J CRAIG (the raiser), Sand Hutton, near York. 2s 6d, or the amount in postage stamps, will be required.

N.B —The most respectable reference as to its superiority given on application.

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	Orange Tubs, Flower Boxes, &c
Garden Edging	

EDWARD EDGE will be happy to answer any inquiries, either personally or by post.

SUPERB HYACINTHS, ANEMONES, TULIPS, &c., just received from the most celebrated growers in Holland, and will be delivered free of all expenses at the railways, packet-offices, or in any part of London, at the very moderate prices annexed.

Messrs SUTTON and SONS, Reading, Berks, respectfully present the above as a select list of the sorts most worthy of cultivation, and recommend early application, while they possess fine roots of every variety

N B —Parcels delivered free to any part of London, and properly packed for conveyance to any distance

Sales by Auction.

TO GENTLEMEN, BUILDERS, NURSERYMEN, & OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed to Sell by Public Auction (under a bill of sale), on the premises, Sussex Nursery, Loughboro' road, Brixton-road, on Monday 30th September, 1844, at eleven o'clock, the whole of the NURSERY STOCK, consisting in choice Evergreens and Flowering Shrubs, Standard and Dwarf Roses; also, two newly erected Greenhouses, Frames, about 2000 Greenhouse Plants, a quantity of Rock Work, Utensils in Trade, &c, may be viewed prior to the sale Catalogues may be had on the premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone

FREEHOLD NURSERY GROUND, ST ALBANS, HERTS

MESSRS PROTHEROE & MORRIS have received instructions from the Executors of the late Mr. Robert Tullwood, the mortgagee, to submit to public competition at the Auction Mart Bartholomew Lane on Thursday, 3d October 1844 at One o'clock, THE KEY FIELD NURSERY AND NURSERY PREMISES, adjoining the town of St Alban's, comprising a comfortable and convenient Dwelling house and Shop, fronting the High Road from St Alban's to London, and about six acres of very productive Nursery and Garden Ground The whole Freehold and Land Tax redeemed and immediate possession may be had The Premises were late in the occupation of Mr. David Watson, who for many years and up to the period of his death carried on the business of a Nursery and Seedsman May be viewed at any time and particulars had at the principal Inns in the neighbourhood, at the Auction Mart of J S Story, Esq, Solicitor St Alban's, of George Drew, Esq, 185, Bermondsey-street Borough and of the Auctioneers, Leytonstone, Essex

BUNNEY'S FINAL SALE.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, BUILDERS, AND OTHERS

MESSRS PROTHEROE AND MORRIS are instructed by the Proprietor (in consequence of the Lease having expired), to submit to Public Competition by Auction, on the Premises, Kingsland Nursery, Balls Pond road, on MONDAY, Oct 7, 1844, and following days, at Eleven o'Clock each day without reserve, the whole of the valuable NURSERY STOCK, consisting of FRUIT AND FOREST TREES, a considerable quantity of EVERGREENS, AMERICAN PLANTS, STOOLS, &c The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their Grounds; also the Trade, from its excellence, and comprising an excellent collection of Ghent AZALEAS, MAGNOLIAS RHODODENDRONS, &c May be viewed prior to Sale. Catalogues may be had on the Premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone

ISLINGTON NURSERY.

TO NOBLEMEN, GENTLEMEN, NURSERYMEN, and Others.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor to submit to Public Competition, on MONDAY, 14th October, 1844, and 2 following days, at 11 o'clock, (in consequence of the ground being required for building,) a portion of the valuable NURSERY STOCK, consisting of about five thousand Belgian Azaleas, in 40 fine varieties; several thousands fine Hybrid Rhododendrons, well furnished with bloom buds, Green and Var Hollies, Chinese and Siberian Arborvitæ, about five thousand Laurels, with a fine assortment of Fruit and Forest Trees, Flowering Shrubs, &c.

May be viewed prior to the Sale. Catalogues may be had on the Premises, of the principal Seedsmen; and of the Auctioneers, American Nursery, Leytonstone.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by Mr FRANKLIN (in consequence of his Lease having expired and the ground let for building) to submit to Public Competition, on the Premises, Cottage-place, City Road, on THURSDAY, October 17th, 1844, at 11 o'clock, the whole of his VALUABLE STOCK, consisting of named Seedling Tulips, Auriculas, Carnations, Picotees, and Pinks, Greenhouse and Herbaceous Plants; a capital Greenhouse, 30 ft. by 11 ft.; and sundry Effects. May be viewed prior to sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, Leytonstone.

PELARGONIUM "CELESTIAL."

CHANDLER AND SONS, Nurserymen, Vauxhall, London, have now ready to send out young plants of their New Geranium "CELESTIAL," which has been so much admired. The flowers being very large, and with a beautiful white throat, it is one of the most conspicuous variation that has yet been raised. Plants, 10s. 6d. each.

C. and Sons have also to offer healthy young plants of CAMELLIAS of sorts, with flower-buds, at 36s. per dozen; larger plants 42s. per dozen; and good plants of the newer sorts 60s. per dozen. Also good plants of the best sorts of CHRYSANTHEMUMS, at 12s. per dozen; larger plants, 18s. per dozen. The package included in the above prices. A remittance or reference for payment in London will be expected from unknown correspondents.

WOODLANDS NURSERY, Mayfield, near Uckfield, Sussex.

WM. WOOD AND SON have the pleasure of offering the following choice CAMELLIAS, which are chiefly strong plants abundantly furnished with bloom-buds. They also beg to inform Amateurs who are desirous of purchasing Camellias for flowering this season, that they will now bear the transit better than when the buds are in a more advanced state.

Candidissima per plant—5s. 6d.			Leana superba, p. plant 5s. 6d.

" alba	3	6	the above for	45	0

W. W. and Son have also an extensive collection of new and popular varieties, priced Catalogues of which may be had gratis on application. Plants will be presented to compensate for carriage. A remittance or reference is respectfully solicited from unknown correspondents.

The Gardeners' Chronicle.

SATURDAY, SEPTEMBER 28, 1844.

MEETINGS FOR THE FOLLOWING WEEK.

Tuesday,	Oct. 1	Horticultural	3 P.M.
Friday,	Oct. 4	Botanical	3 P.M.

ANY improvement that can be effected in the quality of POTATOES is important. Some observations on the subject, at this season of the year, may possibly therefore have a useful tendency.

It is well known that in some soils, and in most seasons, the produce of Potatoes is abundant and their quality excellent; while in others, the quantity is not deficient, but the quality is inferior; and there are situations so unfavourable, that the crop is always bad in every respect. Occasionally, indeed, cold wet seasons deteriorate this important crop, even in the best soil on which the most skilful cultivation has been bestowed. Supposing, however, that all has been done which could possibly be effected in the way of good cultivation, yet, when the crop is fit for taking up, its proper after-management is a most important consideration.

People think that if they guard their crop from frost, they have done all that can be needed; but this is a mistake of the worst kind. By improper management after taking up, Potatoes of the finest quality are easily spoiled; and, on the contrary, by judicious treatment, even such as are watery may be much improved. It is of the first consequence that light as well as frost should be guarded against, for light renders the tubers unwholesome, and that in proportion to its intensity and the length of time the tubers are exposed to its influence.

The stems, and in fact all the parts of the Potato-plant above ground are more or less poisonous. Tubers are occasionally formed along the stem, but they are, as we all know, green and bad. This is entirely owing to their exposure to light; for had the stems been laid in the earth, so as to have covered such stem-tubers from the commencement of their growth, they would have been just as good as the tubers of the usual underground formation. On the contrary, tubers naturally produced from a part of the stem below the surface, although they may be of various colours outwardly, are blanched internally, unless they grow themselves out of the soil. In that case they acquire a green tinge throughout, and with it a quality bad, like that of the spurious tubers produced in full daylight on the stem above ground.

It is, fortunately, not much the practice now; but formerly in towns, and in London particularly, large heaps of washed Potatoes were to be seen exposed for sale and to the action of light, and in some situations, occasionally to the direct rays of the sun. Potatoes, even in their dirty state, as taken up, will be considerably altered in colour, both externally and internally, and proportionably impaired in quality by a few days' exposure to light in clear weather, although they may not be exposed to the sun's direct rays; but the effect must be much greater when the surface is washed and deprived of the partial shade afforded by the particles of soil.

On the part of the vendors, it may be argued that exposure is necessary for sale; but this argument would soon fall to the ground were purchasers aware that, all other circumstances being the same, Potatoes which have suffered the least possible exposure are the best for food, and *vice versâ*.

The time was when Potatoes were in many instances spread out in the sun, in order to dry them before storing in the earth. No practice could be worse, for the reasons above stated; and, moreover, the object in view, that of rendering them ultimately drier and better in quality, was not attained. On the contrary, although deprived of a portion of their moisture in the first instance, yet this only left room for the absorption of moisture contaminated with gases generated in the cave. Such gases will be generated in greater quantity if straw, or other vegetable substances, apt to decay, are employed as a covering next the Potatoes. Fine white-fleshed Kidney Potatoes have been known to be tinged yellow throughout in consequence of having been covered with straw. The straw was no doubt dry when used, but it soon acquired damp, and the conditions of decay, from the layer of earth resting upon it. Potatoes so tainted are said to taste of straw, or, in other words, to possess that well-known musty flavour which decaying straw communicates. The bad quality imparted being so easily traced to this material, it is surprising that straw should continue to be so much employed in contact with Potatoes.

Some persons may perhaps grant that the least possible exposure to light should take place between taking up and storing, and yet may consider it necessary that Potatoes taken up in a very wet state should be dried previously to being stored, in order to avoid a greater evil than that resulting from exposure, namely, their rotting. It has, however, been found, that although Potatoes were taken up and immediately stored in the earth, in moderate quantities, with the mud so wet as to be dripping through the baskets, yet those Potatoes presented as dry an appearance when uncovered in spring as others that were stored in a dry condition. In the former case it may be presumed that part of the excess of moisture would descend to the bottom of the pit and there drain off; moreover, that when the covering of earth became colder than the Potatoes and the water on their surfaces, the latter would be gradually condensed on the particles of surrounding soil, the process continuing so long as the tubers maintained a higher degree of temperature.

As the season for taking up the crop is approaching, the preceding observations may be turned to account by secluding the tubers from light as expeditiously as possible. To do this will require little or no additional expense; while great superiority in the quality of the crop will be insured.

Having thus pointed out one of the sources of deterioration, it may be as well to name a means of improvement. Always dry the tubers before cooking them—still, however, in the dark. If a Potato is weighed when fresh taken up, then laid in a dry warm place for some time, and again weighed, it will be found to have become lighter in consequence of the evaporation of a portion of its water, and it will then in boiling be more flowery. In Ireland, with this in view, Potatoes, when watery, are often taken out of the caves and kept in a dry place for a few weeks, and a great improvement is the consequence. The French are aware of the same fact. A writer in the *Revue Horticole* says—"In unfavourable seasons, Potatoes are often found to be watery and without flavour, although cooked with the greatest care. In this case the mode of effecting an amelioration is easy; it consists in placing them near a stove or oven for about a week previously to their being used. At the end of that time they will be found mealy and of good flavour." Objects of vast importance are sometimes attained by very simple means; and we regard that to which the foregoing remarks apply as one by no means undeserving consideration.—*R.*

REMARKS ON Mr. HOARE'S NEW BOOK ON THE VINE.

I HAVE just met, for the first time, with this book; and, with all due deference to Mr. Hoare, I would wish to make a few remarks on certain passages. Before venturing, however, on such a liberty I must observe, that so far from denying any of the first principles in the cultivation of this valuable fruit, on which Mr. H. takes his stand, I would wish to add my testimony to their immense importance. No writer has, in my opinion, ever thrown so much light on the habits of the Vine before, and his work will, I make no doubt, silently effect as great a change in the culture of Vines (confined as it has been to mere rules), as Mr. Hamilton's book is likely to do in the culture of the Pine-apple, when his system shall be thoroughly appreciated. New systems, however, frequently push things to inconvenient extremes; and it is this that I wish to notice.

Constant and uniform action of root in the growing season is, no doubt, as Mr. H. justly observes, the great desideratum; the greatest obstacle to this in our climate is undoubtedly those dashing rains which occur in most summers, and by which the ground is saturated and choked for sometimes a week or a fortnight together; in which case those borders must be well drained and constituted indeed, in which the rootlets do not become discoloured and lose part of their lively action. Thorough drainage, shallow borders of not more than a foot, a due attention to the mechanical texture of the soil, with a judicious application of top-dressings of rich rotten manure in times of drought, will be found, I imagine, the surest recipe in our cool and damp climate.

I should recommend those inexperienced in Vine-border making, to compromise Mr. H.'s plan, by using abundance of his materials at the bottom of the compost over the drainage, and uniting the well-known permanency of chopped turf from very old pastures, with the porosity of the other materials, for one foot on the surface. In this case it would be advisable to use Mr. H.'s rough materials in larger lumps.

At page 21 of Mr. Hoare's work he makes some excellent remarks on what takes place in the great majority of cases with early-forced Vines, the roots of which are outside. But here I conceive that in adhering too tenaciously to his own doctrines, he has, with that ardour peculiar to those who make new discoveries, somewhat overcharged the consequences of the old and erroneous method. Erroneous! Yet, strange to say, excellent Grapes have been obtained by it, and that in a host of cases. Not that I would by any means advocate it, but all facts bearing on so important a subject should be freely stated.

Now, Mr. H. seems to consider that it is what he terms "the maturative power" alone that is drawn upon in this case, and that the vegetative power has no part or lot in the affair. Now, the Scotch folk have a saying, I think, that will nearly describe the position such Vines are placed in, viz., "all going out of the meal tub, and none putting in, soon gets to the bottom."

I have seen an old Willow truncheon as thick as any ordinary-sized tree, lie in a humid situation after being felled, and there vegetate for several years. However, had this Willow carried annually many pounds weight of fruit in such a situation, it would, I have no doubt, received its *quietus* betimes.

If, therefore, the following quotations be correct, a Vine truncheon would force as well as an established plant with roots. Thus, Mr. H. on this subject says:—"Unless, therefore, artificial means be used to make the roots move before their natural time, an early-forced Vine will present the very singular anomaly of having produced a vast mass of foliage and a matured crop of Grapes, before the roots can have contributed anything towards their support."

I have been thus prolix merely to exhibit the case fairly, and to say in conclusion, that in my opinion the reciprocal action between root and branches is much greater than Mr. H. supposes; or Vines that have come "within our ken" could never have existed as they have done, and yet carry crops. The vital energies of plants are amazing, or how could they contend with the various difficulties with which they are beset?

Mr. H., at this section of his book, speaks of short-jointed wood, the well known criterion of fruitfulness in most trees. In allusion to a bundle of Vine cuttings received from Spain, he most judiciously describes, and proves the influence of heat (day?), and more especially light, in producing such wood. This is all excellent; and I could only lament one thing, viz., his omission of the injurious effects of overhigh night temperature, about which he has said nothing. Now, the matters of heat and light being entirely relative, are not to be handled in an abstract and cursory way. However, we have been so long hedged about with mere rules, that we dare not boldly descend to the night temperature which Nature herself prescribes; and why? If we should fail, all the world would laugh, while our employers would frown. Now, having less solar light in the day than in tropical climates, there exists a greater occasion for even less night heat than nature points to, in those climes where the Vine in indigenous.

At page 15, Mr. H. says:—"In no part of the world can a Vine be made to produce a single Grape more than it otherwise would do, by the exclusive agency of anything added to the soil, in the shape of a stimulant, except under the circumstances hereafter mentioned." Admitted: but stimulants may, in this case, yea, and do increase the size of the berry, and consequently the ultimate produce; and fine swelled berries are, and perhaps ever will be, highly esteemed.

I have much doubt about the utility of Mr. H.'s cylinders, or columns, of which he treats at page 64. This mode, by its simplicity, may recommend itself in some of the southern counties, but can never spread very far. Absorption of heat during sunshine, and the consequent radiation after, enhancing the value of the atmosphere in the immediate neighbourhood of the absorption, is of such value to tender fruits, that no plan by which the solar heat may be dispersed as fast as it accumulates, can be expected to answer; and this objection I imagine the column would be liable to. Blow from what quarter it choosed, the wind would eddy round the column.

I feel assured that shanking, shrivelling, want of colour, and a host of other evils, are produced by irregular and imperfect action of the root in the growing season; chiefly through glutting rains causing for a while utter stagnation in soils of bad mechanical construction, almost impervious to the atmosphere, and of course averse to the passage of moisture. I care little in comparison about the imagined evils of inside temperature, only do not burn the leaves for want of air, or keep too high a night temperature, and the rest I would regard as secondary considerations.—*Robert Errington, Oulton.* [We are glad to find an experienced gardener like Mr. E. entertain opinions so similar to our own, which were printed before the above observations reached us.]

PRUNING FOREST-TREES, AS PRACTISED BY Dr. THACKERAY IN HIS PLANTATIONS AT NERQUIS, IN FLINTSHIRE.

A GREAT deal having lately been written in praise of these plantations, and about the mode of pruning them

and conceiving from what had been reported of them that Dr. T.'s system of pruning was nearly similar to mine, which I have proved to be good, and have practised when opportunities offered, I was induced lately to go and see them, in order that I might judge for myself. I must say, however, that I was a little disappointed; but I, nevertheless, saw much to admire and praise.

The system of pruning pursued by *Dr. T. is à la Pontey* in the extreme, only in a different guise. The periods, seasons, and manner in which the operation is performed do not alter the nature of the system; and the same notion seems to be entertained as that of Pontey, viz., that the divesting a tree of its side branches increases the weight or bulk of timber in the trunk.

Dr. Thackeray and his panegyrists appear to think that the increase of timber in the trunk arises from the consolidation of what is termed the true sap or cambium in its descent, after it has been elaborated by the leaves; and that the sap is acquired chiefly by the roots from the soil. Now I am of a very different opinion; and have demonstrated by experiments—the results of which I have published in tables in a book entitled "*Facts, Hints, &c.*," about 20 years ago—that the increase of the girth, or circumference of the trunk of trees, depends entirely on the number and healthiness of the branches and leaves. I have there also shown, beyond a doubt, that Larches with numerous healthy branches and leaves increase in girth upwards of two inches annually, and that those having diseased leaves and only a few branches increase very little, if anything, in a season in girth. The same fact holds good with other trees. I could get up a tree in an exposed open situation as tall and slender as in a crowded plantation, merely by divesting it of its side branches as they are produced. As the increase of the timber in the trunk and branches is formed by the descending filaments or woody tissue from the annually-produced leaf-buds and shoots, and as every leaf-bud is a new member, and every branch a family, and the whole together a nation, as it were; therefore, to make it a large and strong tree, increase by all possible means the number and healthiness of the branches and leaves. Lopping off branches as they are produced, or too soon afterwards, makes trees tall, weak, puny things; in fact, you may get trees to grow as tall and slender, and that in a very short period, merely by divesting them prematurely of their side branches, as when they are growing in a crowded plantation without having been timely thinned out.

Dr. Thackeray's system of pruning is tolerably correct, but it is unmercifully overdone. I perceived that some parts of the plantations had been too long neglected before they had been thinned and pruned. Near the rides or roads there are certainly some fine Oak and Ash-trees; and the greater part of the Larches are good, but they are not what they might have been, and undoubtedly would have been, under a better system. With the exception of the specimens already mentioned, the greater part of the Oaks and Ash are not fine trees, and evidently show signs of having been injured by the Larches not having been sooner thinned out from among them, and also from having been pruned to excess; one object is, however, gained, viz. tall, straight, slender trees without side-branches, to a certain height, and which are only fit for ladders, rails, poles, or such like purposes.

Now, let any one who disputes what I have advanced concerning the increase of timber in the trunk, cut down a tree having numerous branches on one side and only a few on the other, and they will then see that the concentric annual rings are much wider on the side having the greater number of branches than on the other. I would also refer those who are sceptical to the indisputable demonstrations of the rapid growth of timber in trees having numerous branches, published last year in a pamphlet, by J. Hamerton, Esq.

The late writers who praise Dr. T.'s mode of pruning, all advocate the same thing, namely, that the increase of timber in the trunk is obtained from the sap derived from the soil, and that branches prevent the increase of timber in the trunk: they say that branches draw the sap from the trunk. This opinion I was accused of entertaining 24 years ago, when I began to foreshorten branches of the Larch where they had made vigorous and numerous shoots; and this was what induced me to make the experiments which I have published. Now I am fully convinced of the fact that the increase of timber in the trunk and branches is made by the descending filaments or woody tissue, from the annual leaf-buds and shoots. From the conflicting opinions about the pruning of forest-trees lately, I have avoided using the term pruning as much as possible, and substituted training of forest-trees in its stead. My system is to increase the number of branches when necessary, and to keep them of proper dimensions, and within a moderate compass, so as to insure a proper thickness and elongation of the stem, according to the kinds of trees and future purposes for which they may be required; but I never, by pruning off the side branches, deprive trees of the very means of increasing the trunk till that object is attained, and other branches produced to supply their places, when some of them might be taken off, or suffered to decay of themselves according to circumstances and the nature of the trees.

Dr. T. and the advocates of his mode of pruning, imagine that because he prunes his trees every year, and at all seasons of the year, and not at certain seasons or stated periods, that his method must be different from Pontey's and his copiers, but the result is the same in both cases; by cutting off the branches he deprives the tree of the means of increasing the timber in the trunk. I would not have noticed this subject again, had I not been convinced that the system is apt to establish a very erroneous mode of pruning, wholly opposed to the true means of increasing useful and valuable timber.

To contrast Dr. T.'s plantations with others very much neglected that are near them, and that were planted at the same time—as Mr. Scott Russell and some others have done—is not the way to form a correct opinion of their merits.

Notwithstanding the reported superiority of the treatment of the trees at Nerquis, compare them with some others I shall mention, on which no particular care or skill has been bestowed, but which have been left to struggle on as they could in crowded plantations, and see what the results are. The trees at Nerquis have been planted about 28 or 30 years. I took the circumference of two trees at four feet from the ground—a Larch and an Oak. They were considered to be among the best specimens; the Larch was 3 feet 2 inches in girth, and the Oak was 1 foot 7 inches in girth. There were some Ash trees about the same dimensions as those of the Oaks. The finest Larches would probably average from 2 feet to 3 feet in girth, and some of the Oaks from 1 foot to 1 foot 6 or 7 inches in girth. Now in a plantation—the property of Sir W. W. Wynne, in this neighbourhood on the side of a hill of a considerable elevation, and exposed to cold boisterous breezes from the Welsh mountains—I have lately measured trees, planted about 30 years ago, which have received no pruning, but have been occasionally thinned, the girth of which, at four feet from the ground, is as follows:—

Larches from . . 3 ft. 3 in. to 4 ft. 7 in.
Oaks „ „ 2 ft. 6 in. to 2 ft. 7 in.
Ash „ „ 2 ft. 3 in. to 2 ft. 11 in.
And Elms were about 2 ft. 7 in. in girth.

These trees are as tall or taller than Dr. Thackeray's; in proportion to the branches on them the girth is invariably increased or diminished.

Larches are on an average from 3 ft. to 4 ft. 6 in. in girth.
Oaks are from . . . 2 ft. to 2 ft. 7 in. „
And Ash are from . . 2 ft. to 2 ft. 10 in. „

In another plantation at Llanforda, belonging to Sir H. Wynne, which is, however, certainly in a more favourable situation, and has a better aspect, there are trees planted about 28 years ago, on which no pruning has been performed, but which have been occasionally moderately thinned; the measurement of which, at 4 feet from the ground, is as follows:—viz.: Larches, 3 ft. 4 in., 4 ft., and 4 ft. 3 in., with numerous branches down nearly to the bottom; an Elm was 3 ft. 1 in. in girth; a Turkey Oak, 2 ft. 9 in.; common Oaks, 2 ft. 6 in., 2 ft. 8 in., and 2 ft. 10 in.; and a Spanish Chesnut, 2 ft. 6 in. At the same place a Silver Fir, planted in a shrubbery about 22 years ago, measures in girth 4 ft. 1 in.; all its branches annually increase in girth about 2 in. and 2-eighths; two Turkey Oaks, planted 22 years ago, are 3 ft. 7 in., and 3 ft. 8 in. in girth; all the branches annually increase in thickness about 2 inches. In a third plantation, the property of W. O. Gore, Esq., M.P. (an extensive planter), there is a noble Larch that was planted about 40 years ago. It measures in girth, at 4 ft. from the ground, 5 ft. 1 in., and contains fully 40 ft. of cubic timber. This shows what might be done under proper management. This tree, by mere chance, had never been over-crowded, and it was never pruned. In the same plantation, and under the same circumstances, is a Spruce Fir, which girths 5 ft. 3 in.; it is furnished with nearly all its branches. The staple and permanent trees here are chiefly Oaks, a very few of which measure from 2 ft. 6 in. to 3 ft. 3 in. in girth. The average girth is from 1 ft. 6 in. to 2 ft. 6 in. The trees are tall, and are drawn up weakly, with but few side-branches and not much top; all this results from the want of timely thinning and training. The slow growth in trunks of the Oak-trees is occasioned solely by neglect and want of skill; they ought to have averaged from 3 ft. to 4 ft. in girth during that time. The same result, to some extent, happens in Dr. T.'s plantations, on account of his mode of pruning.

Only imagine having a plantation of Larch at 40 years' growth, with from 140 to 200 trees on an acre, each containing 40 ft. of cubic timber; and I have no doubt but that an acre would produce and bring to maturity that number of Larches, as the trees would only be from 15 to 18 ft. apart, allowing the branches to extend each way from 2½ to 3 yards from the bole. And look again at another plantation, consisting chiefly of Larches, belonging to the same gentleman, on a high and very exposed situation, that have been planted about 24 years, and that are nearly all greatly injured for want of timely thinning—the very largest trees of which, and of those only a very few, measure 2 ft. 1 in., 2 ft. 7 in., and 2 ft. 9 in. in girth, at 4 feet from the ground. Again, at the Hayes, near Oswestry, in a very favourable situation as to soil, climate, and aspect, there is a plantation of Larches which have been planted 35 years; the ground on which they grow was previously an Oak wood. These Larches have been pruned much more severely than Dr. T.'s; they measure, at 4 feet from the ground, only 1 ft. 10 in., 2 ft. 1 in., and 2 ft. 9 in. in girth: reflect on this fact; Pontey is here exceeded. At the same place, and very near these Larches, is a Cedar of Lebanon; whose age, counting from the time seed was sown in a bed to the present time, is about 32 years; it measures 12 ft. in circumference, at 4 ft. from the ground. This, taking into consideration the slow growth in its infancy, is not much less than 2 inches of increase in girth annually. There are also here a Scotch Fir, 9 ft. in girth; a Larch, 9 ft. 1 in. in girth; and an evergreen Oak, 5 ft. 6 in. in girth. These are supposed to have been planted at the same time as the Cedar. They are growing singly, and have numerous branches. The length of the bole, from the ground to the first branch on each, is between 11 and 12 ft. That which has been spent in forming large branches might by art have been made to form valuable timber in an elongated trunk. I have mentioned these instances to show what a rapid growing tree the Cedar of Lebanon is, under favourable circumstances; and to contrast the difference between the preventive system of pruning, and pruning every year, and at all seasons of the year. This mode of pruning is generally understood to reduce the number of branches, instead of increasing and modifying them, and in that lies the error.

The following is a statement of the girth and height of some of the trees in the Royal Forests. They were planted about the same time as the Nerquis plantations, as will be seen by the dates. The measurement in girth was taken at 4 feet from the ground. Chopwell woods were planted in the years 1813-14-15. The size of trees in them, measured September, 1844, was—

	Girth. ft.	Girth. in.	Height. ft.
Larches	3	0	30
Elm	3	0	30
Oaks	2	4	21
Ash	2	3	18

Chopwell lies east of Carlisle, and is as cold, late, and bleak as North Wales. Nerquis lies west from Cheshire, and is bleak and cold. Dean Forest is situated in the southern part of South Wales; the situation is hilly and bleak. The following is the girth and height of trees in Dean Forest:—

		Girth. ft.	Girth. in.	hgt. ft.
1. Stapledge Hill, planted 1814.				
Oaks	1	2	5	32
	2	2	2	34
	3	2	7	37
2. Haywood Hill, 1810-11.				
Oaks	1	2	6	30
	2	2	3	30
	3	2	1	31
Larch	1	2	9	35
	2	2	8	31
	3	2	9	31
3. Blakeney Hill, 1813.				
Oaks	1	2	5	34
	2	2	6	35
	3	2	4	33
Spanish Chesnut	1	2	11	37
	*2	3	9	36
	*3	4	1	39
Ash	1	1	10	39
	2	1	8	33
	3	2	0	33
3. Barnhill, 1810.				
Oaks	1	2	10	36
	2	3	11	34
	3	3	3	34
Spanish Chesnut	*1	5	2	38?
	2	3	4	36
	*3	4	8	40
Spruce Fir	*1	4	6	41
	2	4	0	42
	*3	4	6	43
4. Bromley Hill, 1812.				
Oaks	1	3	2	39
	2	3	10	40
	3	3	8	37
Spanish Chesnut	*1	3	7	40
	2	3	0	38
	*3	3	11½	39
Spruce Fir	1	3	2	39
	2	3	3	39
	3	2	9	38

Compare these trees with those at Nerquis—with the Larches at the Hayes—or with Oaks of 40 years' growth in Mr. Gore's plantations. Look at Barnhill, where a Chesnut only 34 years old measures in girth 5 feet 2 inches, and is nearly 40 feet in height, making an annual increase in girth of about 2½ inches; a Spruce Fir 4 feet 6 inches in girth, and 41 feet in height; and Oaks 3 feet 3 inches in girth, and 34 feet in height. At Bromley-hill, Oaks of 32 years' growth are 3 feet 2 inches in girth, and measure nearly 40 feet in height; in Chopwell woods, at 30 years old, they are 2 feet 4 inches in girth. It should be mentioned that the Oaks when planted in the Forest of Dean were much injured and destroyed by mice. I have little doubt but that I could have found Oaks, both in Dean Forest and in Chopwell woods, of larger dimensions; but it was my wish that the measurement should be taken from trees growing in the most exposed places, and at about the same altitude as those at Nerquis. Nearly all the Larches in these woods have been cut down, and no doubt the best were selected from among them. The trees in the Nerquis plantations have been divested of their side branches, from 15 feet to 20 feet in height on an average.

In conclusion, I protest against the "non-pruning advocates;" the adhering too closely to that doctrine is productive in most cases of as much injury to the real bulk and value of timber as over-pruning is. It is best to pursue a middle line between the two extremes, which is the preventive system of pruning. It is clear that we may regulate by skill and art the increase of the girth and elongation of the trunks to almost any proportions we please.—*W. Billington, Underhill, Oswestry, Salop.*

WEATHER-WISDOM.

The vicissitudes of the seasons having such a powerful influence on the fortunes of the husbandman and the gardener, and modifying so much all the other employments and amusements of life, we cannot wonder that the universal propensity of human nature to pry into futurity should be exercised in the species of divination which has been rather quaintly, and with an air of sarcasm, called Weather-wisdom. It is curious to study the gradations of this folly, from the lofty delusions of Imlac's mad philosopher, who could "restrain the rage of the Dog-star, and mitigate the fervours of the Crab," and of the "Great Medicine," who brings rain on the prairies, down to the humble speculations of him who "thinks that it will rain because it looks black," or that "it will be fine to-morrow because the sun goes down red." But is it not surprising that notwithstanding the frequent failures of the most observant and best judging of this class of prophets, and the general conviction of well-informed persons of the utter futility of the predictions of meteorology, except as regard the broadest features of the year, from day to day we hear a repetition of the same absurdities?—not such as are silly and hastily broached in the greetings of casual rencontres, but gravely stated and put into print with all the solemnity of truth and

sound philosophy. Here is a specimen which I find in the "Spectator" of Sept. 7, copied from the "Nottingham Review," and which, if a paper of the "Spectator's" character thought worthy of notice at all, ought not to have allowed to go to its readers without denouncing as nonsense, all, at least, but the fact:—

"On Sunday last a large flock of wild geese passed over Chesterfield, on their way, it is supposed, to the fens of Lincolnshire. Such a circumstance at this early period of the season was hardly ever known, and it is considered to forebode an early and severe winter."

Not an autumn passes but we hear of such prognostics of a forthcoming hard winter, in spite of our experience of the fact, that five times out of six such prognostics fail; for it is only about once in as many years that we do have a severe winter. The temptation to this affectation of superior knowledge is so strong, that men even who are apparently engaged in the right road of investigation, and conversant with the means by which the exact results of meteorological observation are obtained, are led astray by it.

Articles appear from time to time in the *Times*, under the head of "London Weather," and are advanced by that useful paper with a show of a faithful record of facts, and reasonable deductions therefrom, on known philosophical principles. The author of these papers often betrays a disposition to foretell the chances of a few days prospectively. About a week ago we were told that certain electrical conditions of the atmosphere existed, and that a gale was probably at hand. Now I would challenge the writer to show what are the express electrical phenomena indicative of an approaching gale, which do not frequently exist without any such result—for no great atmospheric changes take place without manifestations of electric agency. The prediction was a tolerably safe one; for who does not know that the equinox is come, and that the month of September seldom goes out without a little foretaste of the agitations of the declining year!

If we are ever to have anything better than an empirical knowledge of the course of our seasons, it would be better to refrain from such pretensions till they can be warranted by well-grounded deductions from a long series of recorded facts and observations, collected simultaneously (as they must be, to be of any use) at many and widely-extended points. One of the most remarkable instances of the danger of venturing on this species of vaticination I remember to have happened about the years 1814 or 1815. Two or three succeeding summers had been excessively wet and cold, and an article appeared in the "Quarterly Review," in which conjectures were advanced respecting the concomitant existence of a greater than usual extension of the ice of the Northern Atlantic, and with a confident prediction that, as icebergs were still floating in very low latitudes, we must expect to suffer a continuance of the evil for one more season at least. This article had hardly reached the public when there commenced one of the warmest and finest summers ever known, (I think the summer of 1816). It begun in May, of which the first part was wet and warm; it cleared up about the middle of the month, and it continued almost uninterrupted sunshine till after harvest: the Pomegranate was ripened in the south of England, and Melons were raised with no other artificial help than the protection of a handglass. The succeeding autumn was beautiful, and the winter mild.

In concluding these cursory observations on so important a subject in all the relations of rural life as meteorology, permit me to express a hope that you will, ere long, indulge us with a Paper, or series of Papers, on the actual condition of our knowledge of this branch of natural history, and of the best means of advancing it—"how to observe in meteorology." We shall then better know our ignorance, and learn to avoid the gross absurdities of prediction—to assign the simple facts of the flight of birds, when assisted by favouring currents of wind, to their true cause, the everlasting search for food; and the accidental profusion of Hips and Haws, and other comestables, to the immediate and obvious effects of well-ripened wood, and a good blooming time. I will do the gardeners of my acquaintance, and many of the farmers too, the justice to say, that the affectation we are speaking of is not very prevalent amongst them; they act, for the most part, on the spur of the occasion, and are watchful of immediate indications of change: they know that "there shall be seed-time and harvest," and they learn to "trust in God;" and, in a better sense than the maxim was once used in, "keep their powder dry." "Don't talk to me of the moons, and of the signs of the weather," says a shrewd old farmer of my acquaintance; "what you call a sign of rain one day, I will prove to you, by the event, is a sign of fine weather another;" adding, what from its completion I suspect not to be an original joke,—"I am only twelve hours behind the Almanac-maker; he tells you in the morning what I can tell you, perhaps, more accurately at night."—*P. P.*

Home Correspondence.

ERRATUM.—In last week's No., p. 625, col. b, article "Dog Rose," for "*nayyor*" read "*nayyaut*," from *nayyus* (rough).

Horticultural Society of London.—In the *Chronicle* of last week there is a letter from an exhibitor of fruit respecting the prizes offered by this Society for next year. It appears that so long as fruit-growers are quiet, no additional rewards will be offered, while the plant-growers obtain all they ask. Although, at the last June Exhibition, there was only one large collection of stove and greenhouse plants shown, and one in the class of Heaths, which was not thought worthy of the Gold Medal offered, in the class of six there was not a competitor, this leaving in the classes of stove and greenhouse plants eight medals not awarded. In the classes of Heaths, two of the first prizes were withheld. Notwithstanding all this, considerable additional rewards are offered for next year. The Editor of the *Gardeners' Chronicle*, in 1842, told fruit-growers, in order to induce them to exhibit, that the prizes offered for fruit were equal to those offered for plants. There has been a great alteration on the one side since that period; take, for example, Orchidaceæ, the prizes offered for collections of which, at each Show in that year, amounted to 10*l.*; for collections of fruit, 18*l.* 15*s.* The prizes offered for collections of the former in 1845, at each Show, amounts to 70*l.* 15*s.*; while the fruit remains without alteration, although the fruit tent created intense interest—I think I am justified in saying, even more than those of plants. As far as I saw, there was not a plant of any merit, which had been properly entered, unrewarded, while the fruit-table literally groaned under the weight of meritorious productions, which could not obtain a prize at all. It is well known that one house will produce a collection of Orchidaceæ for each of the Exhibitions, while the fruit-grower must at least have three houses from which to obtain one collection, each of which requires as much skill and attention as the one house of the former. I think—and I imagine that most of my brother gardeners will agree with me—that the additional prizes have been placed where they were least wanted; I have no doubt the reason why fruit-growers do not complain is, that comparatively speaking few of them attend personally, and therefore cannot judge of what is going on. Prizes are offered for the best named plants, while the threat of disqualification is held out to fruit-growers in case their productions are not properly named. In conclusion I may add, that as the Society profess to encourage good gardening only, it is absurd to allow fruiterers to exhibit: there can be no merit in showing other people's productions. Here again the plant-shower is to be protected by a new regulation.—*M. Henderson, Colsorton Gardens.*

[Our correspondent forgets the difference between the expense of bringing a box of fruit and half-a-dozen van-loads of plants. If he compares the cost of carriage with the value of medals to be gained, he will find the balance very much in favour of the fruit-growers.]

Polmaise Heating.—I sent two bunches of Black Hamburgh Grapes to the Horticultural Show in Edinburgh, on the 20th instant, grown in the hothouse at Polmaise, which is heated by means of a circulation of hot air, without either pipes or flues; each bunch weighed upwards of five pounds, and obtained the prize against eight competitors. The Grapes were much admired, both for size and flavour; thereby clearly proving that the system I had adopted was completely successful, and will, I have no doubt, be adopted in future in preference to the old system of flues and pipes—being cheaper and easier managed, requiring less fuel, and incurring no risk of injury to the fruit when blossoming, either from cold air or steaming, when flues are watered in too heated a state. Several of the bunches now on the Vines are about the same size as those sent to the Show.—*Wm. Murray.*

The Polmaise Heating.—I have heard of many strange things in my lifetime; such as a person setting up a man of straw that he might have the pleasure of knocking it down, and of Don Quixote attacking a windmill, and of Hudibras comparing himself with Cæsar; but none of these things are equal to the hallucination that appears to exist in the mental region of the craniums of persons of the present day, respecting the Polmaise System of Heating. In the name of wonder, where has Mr. Glendinning got the idea that "dirty smoke-flues," or "any modification of them," are used in the Vinery at Polmaise? Surely not from anything that has appeared in the *Chronicle*; and he may rest satisfied that there are neither hot-water pipes nor any modification of smoke-flues employed in heating that Vinery. If he has any misgivings on the subject, he might step on board one of the London and Leith steamers, and from that to one of the steamers that sail between Granton and Stirling; and when among the beautiful windings of the Forth, he might be landed within a few yards of the Vinery; any remaining wrong notions will then be quickly dispelled. Mr. G. says, "It is no defence of a system to invoke the crest-fallen appearance of some who considered themselves the best Grape-growers in Scotland." Perhaps not; but what would he say of the gardener who thought he did well when he grew Pine-apples with six pips in height, and then, when a method was shown him of increasing them to twelve pips, instead of adopting the plan, condemns it before he understands it, and with a mind case-hardened with prejudice prefers his own, which is only some remains of the olden time? Surely there is more hope of a progressive being, even though he should be crest-fallen for a time, who can appreciate the invention of his neighbour, than the instinctive being who has only one way of doing his work.—*Peter Mackenzie.*

Destroying Wasps' Nests.—In dry seasons, at the place where I was apprenticed, we generally had a great many wasps' nests in the park and immediate neighbourhood. We were paid sixpence by the gardener for the destruction of each nest. At first we followed the old method of taking them with gunpowder; but wishing to make as much money by them as possible, we discarded gunpowder altogether, and pursued the following plan, which never failed:—Our armoury consisted in a pair of old double-actioned fumigating bellows, fitted with the box and tube; a basket containing some old dry hast-mat, or brown paper; and a small bag with a portion of sulphur; together with a spare basket for the combs, and a spade, lantern, and candle. Thus equipped, when darkness approached we besieged the enemy in the camp. We took off the box from the bellows, and put in the bottom of it a little dry hast-mat, or brown paper, on which we dredged a small quantity of sulphur; we then filled and dredged as before, until we thought we had sufficient material for destroying one nest; we then lighted it with the candle, fitted on the box, and proceeded cautiously to work, the person having the light pointing out the hole, to which we applied the tube of the bellows, and puffed away, taking care not to allow the two sentries to escape that were stationed at the entrance. From the exclusion of the air and the effects of the sulphur, in about three minutes the work of destruction was effected; the combs were then dug out, the suffocated wasps swept back into the hole, which was well trod in the bottom, and then filled up again; after which a wasp was rarely seen again near the place. In about ten minutes we could destroy the strongest nest; so that by this cheap and simple method three young men might destroy an incredible number of nests in one evening after it was dark.—*James Roberts, Hampsthwaite, near Harrowgate.*——*Querous* says—"Wherever the nest is in a cavity without any other hole or fissure, but the one of ingress and egress, about a wine-glassful of spirits of turpentine will effectually settle them. Pour so much in and stop the hole. Where the ground is such as to crack with drought, connected with a drain, or by any means having other openings or air-conductors to the nest, the spirits are rendered ineffective, and the equib of powder and brimstone must then be resorted to."——*Mr. Wighton* adds, "I have lately tried, with success, destroying wasps' nests with spirits of turpentine. In the evening I pour about a common wine-glassful of the spirit into the holes from a long-necked bottle, and close them immediately with a 'bit of turf, beating it firm with the heel.' I dig out the nests on the following morning. With regard to the quantity of spirit required, much depends on how the nests are situated; if in loose dry soil, and their entrances ascend, or if they are horizontal, more is required. In such cases a small squirt, as suggested by Professor Henslow, must be of great use. It must, however, be the smell that is the cause of death; for if the entrance is not closed immediately after the turpentine is poured in, many of the inmates will survive, especially if the nest is situated as already noticed. But though the spirit causes death, and at times even in the larvæ, still those in the pupa state, being defended by their cocoons, may dig their way out; consequently the nests ought to be dug out and destroyed, for the brood reared in autumn are drones and queens, males and females, to insure a future race. There need be little fear of an attack from such of the wasps as are shut out, and which remain about the closed entrance, for they soon lose their courage, and are easily smashed with a spade. I once gave some wasps' nests a dose during the day, and left the entrances open for a while; I found all was silent within, and few or none would enter; in short, many of them dropped down when within range of the holes. I turned out the nests and the paralysed wasps, without being attacked; my only defence was having previously rubbed my hands and face with turpentine. I may observe that there seems to be truth in Mr. Knight's remarks, viz.:—'That if a nest of wasps is approached without alarming the inhabitants, and all communication suddenly cut off between those out of the nest and those within it, no provocation will induce the former to defend it and themselves. But if one escapes from within, it comes with a very different temper.'"——I cannot understand how "H. P." has failed in destroying his wasps' nest with the turpentine-bottle; I have destroyed more than seventy nests by it since I read of the method. The way in which it was used was to rince each bottle (at the time of using) with spirits of turpentine, and insert the neck of the bottle into the mouth of the nest, covering round the hole with any kind of earth. In two or three days afterwards I have proved them to be all dead. Last week one of my men brought me a nest, the combs of which, I am sure, would fill a bushel, and not one wasp or young one alive in it.—*J. H.*

The Thrip.—The following is a simple and effectual mode of destroying this troublesome pest:—I fill the house, pit, or frame, that contains the plants infested, with steam and Tobacco smoke. By this means I give the plants, pots, and stands, and every part of the house a regular dressing of Tobacco water, which completely destroys these insects, and does not in the least injure the plants, not even the most delicate of them. My mode of using it is this:—For a house 43 feet long and 11 feet wide, I take 1 lb. of Tobacco, and having an old wire basket, containing a few hot cinders, I put the Tobacco on them and hang the basket up in the house; I then blow it with bellows until it is well lighted, when I turn on the steam from a small apparatus that I have for the purpose of steaming the plants. The Tobacco will keep burning until it is all consumed. The steam is kept on for about an hour, in which time the plants are covered with dew, which is well mixed with Tobacco smoke. This I repeat on the following day, using only half a pound of Tobacco; and since then I have not seen one thrip in the house. Those who have not got the means of steaming the house from a boiler, will find a trough, with small holes pierced in the bottom, fixed over the hot-water pipes or flues, a very good substitute. Enough of steam will be generated in this way in one hour to cause a fine dew on the plants; if the house or frame can be covered during the operation, so much the better, as it will prevent the steam from condensing on the glass, and also keep the Tobacco smoke from escaping through the laps in the roof.—*R. G.*

Onions.—Does not "W. E." make some mistake in the statement, p. 634, respecting the crop of Onions grown by Mr. Everist? It would be most desirable to be informed of the method by which so very unusual a crop, after the rate of 1416 bushels of 80 lbs. each, or 50½ tons per acre was produced; 2 lbs. 9½ ozs. per square foot could only be the result of some very superior management. Perhaps "W. E." will oblige the readers of the *Chronicle* with particulars.—*Luser.*——Another writer, signing himself "C. W.," states that he is an amateur grower of Onions, and has carried the cultivation of them to great success. The largest of his Onions, English sorts, have this year weighed 14 oz. each. After being dried and trimmed, they were sown in the third week in March. He would be obliged if "W. E." would give the size and weight of the 12 largest, and also the ordinary size of the *Onions*, the number which fill a bushel heaped up, and such other particulars as he may be pleased to afford.

Hybridising Fuchsias.—Our hopes of improvement in Fuchsias lie in mingling the species that now exist: one flower has one desirable quality, another has another—we wish both these to meet in one. This can be obtained by hybridising, or fertilising the seed-vessel of one flower with the pollen of another. To do this regularly and systematically I proceed thus:—I get a small box about 2 inches deep and a foot square, and I divide it into 24 compartments; into each of these I cut a small quantity of worsted thread into pieces about 2 inches long each. The worsted of each compartment is of a different colour, and each colour I use to represent a Fuchsia; for instance, white represents Venus Victrix; orange, fulgens; blue, Formosa elegans; black, Exoniensis; and so forth. Having my worsted ready, I take my box into the greenhouse, and proceed thus with my operation:—I choose a Fuchsia for a female to bear the seed. I examine the plant till I find a perfect flower, newly opened, before the anthers have burst and discharged any of their pollen. I carefully cut off the anthers, and I then select the plant by which it is to be fertilised. I find on it a flower which has its anthers covered with pollen; I pull this, and with it I dust the stigma of the prepared flower, around whose flower-stalk I tie a piece of worsted of the colour that designates the male employed. When I gather the seed, I know by the colour of the worsted at once how it has been fertilised, and I place the seed-vessels in paper boxes to dry, carefully marking on each the names of the male and female parents. In spring I sow the seeds in separate pots, with labels stating particulars; and by this means I hope clearly to ascertain the true result of my experiments, which never could be done if I were to sow my hybridised seed at random. In such case I might obtain a beautiful specimen—I might get excellence of foliage or habit, or size of flower, but here I stop: I could learn nothing further from my success; I could obtain no insight into the means by which I had already succeeded, or was likely to succeed hereafter. In my experiments I have certain objects in view: I want, for instance, to unite the colours of Venus Victrix with the size of Exoniensis. I wish to have Eppsii with a deep-blue corolla, and fulgens with a pale pink or white tube. I cross these with varieties having the qualities I desire; for instance, I cross Venus Victrix with Exoniensis, Eppsii, and Toddiana. Each plant is used alternately as male and female. My object is to retain the colour of Venus Victrix, but to increase the size of the flower. I do not expect to succeed in one year. I find, perhaps, in one plant the tendencies I wish; I pursue my advantage, hybridise this again, and have no doubt of ultimate success. All my experiments I carefully note down in a register, for I have no doubt I shall meet with results I by no means expect; and by knowing how they came, I shall be able to use them to advantage.—*Cavanensis.*

Parrots.—With regard to the management of these, allow me to state how one (an Amazon), which I have had for several years is treated. His food is hemp-seed in one tin, water in another, and nothing else. As soon as the cold weather of spring is over his cage-door is set open, and he lives in the garden and plantation attached to my house in perfect liberty, returning to his cage for food whenever he likes; he helps himself to Gooseberries in their season, and sometimes treats himself to some Apples. He is always in perfect health, and thoroughly enjoys his existence; and adds much to the interest of the garden, by the display of his bright plumage when on the wing; and by his chattering from the trees or house-top.—*P.*——*T. O'Reilly* adds—"I have known the plumage of the lemon-crested cockatoo restored by cutting a nick in the lower beak. In this case the bird had so feathered himself, that he looked like a young hawk, being covered with scarcely anything but down. A large orange-crested, cockatoo acquired a habit of biting its breast, making a frightful sore. I consulted various persons, and accordingly tried Epsom salts and Cayenne pepper-pods, but without effect. I then had a breast-plate made for it, which it was continually trying to pull off. I did not like to have the end of its beak cut off; and at last it became so ill that I had it killed. I attributed this disease to the fact of the servants having given it eggs, butter, and meat. I have now an orange-crested cockatoo, a grey parrot, and a parroquet; they all live on scalded bread with hempseed mixed with it, and have latterly been eating fruit occasionally. They do not have water given to them, but the cockatoo is occasionally indulged with some tea. This mode of treatment seems to suit them."

The Deadly Night-shade.—A few days ago two females from Lancaster were observed in the neighbourhood of Heat Bank gathering and eating the fruit of this plant. This induced two men passing at the time to eat also; one of the men by chance took a few along with him to an inn, and showed them to the landlord, who pronounced them to be poisonous, and recommended a dose of medicine to be immediately taken, which had the desired effect of removing the deadly poison from his body. The other man was not seen until the following day; he was in a state of insensibility, with his eyes closed, and his body was swollen to an extraordinary size; every means were used to save him but without effect, and after lingering three days death terminated his sufferings. The two females, on their return on the same day to Lancaster, were taken alarmingly ill, and a surgeon was instantly called in, who being made acquainted with the fact of their having eaten the berries, immediately applied the usual remedies. For some time there appeared no hopes of recovery; they were in great pain and were quite delirious, and continued so for several hours; but, happily, they both recovered. The Deadly Night-shade is one of the most dangerous of vegetable productions; the berry is, from its fine colour, inviting, and the apparent richness of its juicy pulp, resembling wholesome and more grateful fruit, induces those ignorant of its deadly qualities to taste. It cloys not until the fatal principle is imbibed; its deleterious action is not experienced for many hours; afterwards the victim is overwhelmed with dryness in the mouth, burning pain in the throat and stomach, giddiness, stupor, and is soon unable to account for the calamity which has befallen him. It is to be hoped that this will be a caution to persons gathering and eating wild fruit from the hedge-rows.—*M. Saul.*

Fecundity of the Canary.—There is a person living near Cowley Hall, in the parish of Hillingdon, that has a pair of canaries which have had no less than six nests between the 2d of April and the 4th of this month (September), hatching sixteen canaries, two nightingales, and one green-finch, making in all the large number of nineteen. The whole, with the exception of the nightingales, which by some accident got smothered in the nest, have turned out strong, healthy, birds. The total number of eggs laid by this pair during the season was twenty-four.—*W. M., Hillingdon.*

Societies.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

Sept. 20th—This was the Anniversary Dinner, and as it had been arranged to make the first public exhibition of the bust of Dr. Neill on this occasion, previous to its being placed in the Society's Hall, a numerous and most respectable company assembled. The chair was occupied by Professor Dunbar, who, after having opened the meeting in the usual manner, said—"As Dr. Duncan was the parent and founder of the Society, so does it owe much of its success and prosperity to the exertions and talents of our excellent Secretary, Dr. Neill. The duties of the Secretary are not confined to the mere routine business of the Society. Dr. Neill has had external duties to discharge of a most important kind, and these he has performed to the satisfaction of all parties. He has ever been ready to aid with his advice the efforts of industry and merit, while on the other hand he has soothed disappointed expectations by inspiring the hope of better success on a future occasion. As secretary he has had to conduct a most extensive correspondence with the horticulturists of other countries. He has thus made our Society known in every quarter of the globe, and contributed greatly to bring it to its present prosperous condition. Laborious as these duties and exertions have been for a long series of years, Dr. Neill has most ably and zealously discharged them without fee or reward, though trenching on time most valuable to him in his private affairs; he has done his work *con amore*. Practical gardeners and amateurs owe a debt of gratitude to him for his excellent book on horticulture, which is now one of the standard works on the branch of science of which it treats. I need not say how much the respect we owe the Doctor has been enhanced by his amiable character and unobtrusive manners. He is equally valued as a friend, and respected as a man. In consideration of his valuable services to this Society, several members have desired to have a bust of the Doctor, with the view of its being placed in the hall at the gardens, as a permanent memorial of their gratitude to him." The learned gentleman, after making some observations on the bust, then proposed the health of Dr. Neill, who, much affected, rose and said—"Mr. Chairman, I thank you sincerely for the kind and too flattering way in which you have expressed your opinion of me. I say most truly that I would most willingly have escaped from my present position. I feel totally unable to utter what I feel, I am so overpowered with gratitude. It is little more than a year since I had the honour to receive, in presence of a large number of friends, a splendid piece of plate, the gift of 500 gardeners. To see again assembled so numerous a company for the purpose of bringing forward this bust is perfectly overwhelming, and leaves me almost without words. The chairman rightly observed that I had been secretary for many years, but instead of meriting the testimonials I have received, I have been vastly overpaid in the pleasure I derived from holding the situation. I am deeply grateful for this testimony of respect, which was proposed by Lord Murray, Mr. Fairbairn, and other gentlemen." Some further remarks were offered by Dr. Neill, who concluded amid great applause; and after some other business the meeting closed.

COUNTRY SHOWS.

Bristol and Cornwall Horticultural Society, Sept. 12.—This was the Exhibition; the weather was in every respect favourable, but the attendance was not numerous. The flowers were exceedingly good, and attracted much attention. The fruit and vegetables were also very fine, but not so abundant as in former years. *Fruits.*—*Pine Apple*: 1, highest flavoured and best grown Queen, Mr. Robertson, Esq.; 2, &c., Mr. J. Griffin, gr. to Mrs. Wells. *Melons*: 1, highest flavoured, Green-fleshed, Mr. W. Rundell, Esq.; 2, &c., Mr. W. R. H. Carew, Esq.; 3, &c., &c., Mr. J. Taylor. *Cherries*: the best dish of Morello, Mr. J. Taylor. *Pears.*—The best *Specimen Plant in flower*, not having before obtained a prize (Achimenes splendens), Mr. J. Griffin. Amongst *Stove Plants* from Mr. Rendle's nursery, we noticed some well-grown specimens of Achimenes patens, Gesnera zebrina, Franciscea Hopeana, Russelia juncea, Vinca ocellata, Rivina humilis, Amaryllis Brasiliensis, Gardenia radicans, Pentas carnea, Euphorbia splendens, &c. Among *Fuchsias* were Exoniensis, Defiance, Kentish Bride, Kentish Hero, Prince of Wales, Conservative, Gigantea, Neptune, Florence, Nobilissima, Duke of Wellington, Formosa elegans, Venus Victrix, Fowley's Queen, Paragon, Champion, Magnet, Coronet, Eppsii, Robusta, Britannia, Toddiana, Transparens, Tricolor, Fulgens, Princess, Vesta, Invincible, &c. Besides these, Mr. Rendle also exhibited some seedlings. From the same collection were the following *Dahlias*, viz.—Standard of Perfection, Duranta, Emma Nolke, Lady Antrobus, Lady St. Maur, Orange Superb, Sir J. S. Richardson, Royal Sovereign, Grand Monarch, Sir R. Sale, Cook's Confidence, Prince of Wales, Great Western, Antagonist, Hero of Stonehenge, Admiral Stopford, Thompson's Vivid, Queen of Trumps, Beauty of Sussex, Essex Triumph, King of Lilacs, Prince of Waterloo, Swindon Rival, Orange Superb, Oakley Surprise, Mountjoy's Virgil, Princess Royal, Mrs. Shelly, and Rouge et Noir. Of *Verbenas* he exhibited Atro-sanguinea, Beauty, Boule de Feu, Zenxis, Beauty Blaier, Blue Queen, Striata coccinea, Prince of Wales, and some seedlings.—*Devonport Telegraph.*

Edale Horticultural Society, Sept. 21.—This was the fifth Exhibition during this year, for Dahlias, Carnations, Pansies, Kidney Beans, Celery, Savoys, Broccoli, Red Cabbage, Carrots, Onions, and the best dishes of Apples, Pears, and Plums. The specimens shown were very creditable to the exhibitors, especially when we consider the geographical situation of the place. It is not to be expected but that an elevation of 600 feet above the level of the sea will have a deteriorating influence on the successful cultivation both of flowers and vegetables. The following prizes were awarded — *Dahlias*: Mr. G. Taylor. *Carnations & Picotees*, and *Pansies*. Rev. G. H. M'Gill. *Kidney Beans*: 1, Rev. G. H. M'Gill; 2, Mr. Wigley; 3, Mr. Bardsley. *Celery*: 1, Rev. G. H. M'Gill; 2, D. Christie, Esq. *Broccoli*: 1, Mr. T. Carrington; 2, Rev. G. H. M'Gill; 3, D. Christie, Esq. *Red Cabbages*: 1, Mr. Wigley; 2, Mr. Cooper. *Carrots*: 1, D. Christie, Esq.; 2, Mr. Eyre; 3, Mr. Bardsley. *Onions*: 1, Mr. G. Eyre; 2, Mr. Wigley; 3, Mr. Carrington. *Apples*: 1, Mr. Wigley; 2, Mr. Eyre; 3, Mr. T. Carrington. *Pears*: Mr. Taylor. *Plums*: Mr. Taylor; 2, Mr. Carrington. For Nosegays, three prizes were given: 1, Mrs. J. Christie, 2, Miss Bray; and 3, Miss Taylor.

Sandhurst Floral and Horticultural Society, Sept. 6.—This was the Second Meeting for this year. Among plants we noticed some fine specimens of Orchidaceæ, &c., from Crewe Hall; likewise a beautiful specimen of Fuchsia exoniensis, above 7 feet high, and covered with flowers from the top to the graceful branches hanging round the pot, from the garden of Miss Twemlow. The following is a list of the Prizes awarded:—*Stove Plants*: 1, Miss Twemlow, for Achimenes grandiflora, A. longiflora, and Gloxinia maxima; 2, Mr. T. Stringer, for Vinca alba, V. rosea, and Thunbergia aurantiaca. *Greenhouse Plants*: 1, J. Skerrat, Esq., for Pimelea hispida, Crowea saligna, and Myoporum album; 2, Mr. T Stringer, for Petunia Enchantress, and some others. *Roses in Pots*: 1, Miss Twemlow, for Mrs. Bosanquet, Devoniensis, and Bulgens; 2, Mr. W. Allcock, for Napoleon, Miss Glegg, and Bourbon Queen. *Erica*: J. Skerratt, Esq., for Lamberti, cubica, and Cliffortiana. *Pelargoniums*: 1, Mr. C. Taylor, for Joan of Arc, Comte de Paris, Archduke, Nymph, Clarissa, and Princess Royal; 2, Mr. S. Allcock, for Flash, Nymph, Sultan, Selma, Lord Mayor, and Wizard. *Do.* 3: 1, Miss Twemlow, for Lady Sheppard, Queen of Fairies, and Prince Albert; 2, Miss Twemlow, for Gaines's King, Coronation, and Witch. *Calceolarias*: 1, Miss Tremlow, for Coronation, a Seedling, and Specialis; 2, Mr. S. Allcock, for Modesty, and 2 Seedlings. *Fuchsias*: 1, Miss Twemlow, for Exoniensis, Brookmanii, and Majestica; 2, Mr. C. Taylor, for Exoniensis, Defiance, and Lanei. *Miscellaneous*: Mr W Allcock, for Lilium lancifolium album. *Cornmb*: Mr. G. Bayley. Besides the above there were numerous Prizes awarded for Flowers, Fruits, and Vegetables, the growth of cottagers, whose productions are much improved since this Society has existed. The Prize for the best managed cottager's garden was awarded to Mr. T. Steele.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

CALANTHE MASUCA. Lilac Calanthe. (*Stove Epiphyte.*)—Orchidaceæ. Gynandria Monandria.—This charming plant flowered with Messrs. Rollisson, of Tooting, in June 1843. It is a native of Nepal, and may be regarded as the gayest of the terrestrial species of that rich country, being conspicuous both for the large size of their flowers and their rich colour. From the other purple species allied to it, this is readily known by the leaves as well as by the flowers. *C. versicolor* has leaves smooth on both sides; *C. purpurea* downy on both sides, especially beneath, while this has down only on the under side. *C. versicolor* has white sepals and petals; *C. purpurea* and this, purple ones. While, however, *C. purpurea* agrees in the colour of its flowers, its lip is altogether different, being very narrow, with the lateral lobes quite round. *C. masuca* should be potted in turfy heath-mould, mixed with a few pieces of potsherds. In summer it should receive an ample supply of water at its roots; and where it can be avoided, little should be allowed to fall on its leaves, otherwise the young shoots will damp off. It enjoys a humid atmosphere and a high temperature; but as the leaves are very delicate, they will soon become scorched if shading is not carefully attended to. In winter little water will be required; still, it is necessary to keep the soil damp enough to preserve the bulbs from shrivelling. This is one of the most difficult of Orchidaceous plants to grow well.—*Botanical Register.*

GASTROLOBIUM SPINOSUM. Spinous-leaved Gastrolobium. (*Evergreen Shrub.*) Leguminosæ. Decandria Monogynia.—Of all the plants of this tribe that we are acquainted with, few admit of being more easily reduced to handsome proportions, or have a habit and foliage so neat and unique as this. With a degree of strength and robustness unusual amongst the leguminous plants now abounding in such plentiful variety in our greenhouses, it combines broad and conspicuous leaves, so markedly different in their outline to every other of the same class within the sphere of our knowledge, that whilst they attract notice by their novelty, neatness, and amplitude, they at the same time furnish a distinction so prominently perceptible, that the most cursory observer can never be at a loss to distinguish the plant from those that most nearly resemble it. Till the development of flowers in the spring of the present year afforded the chance of referring it with certainty to its proper station, it was cultivated and generally known as Chorozema oppositifolia, a mistake which most probably arose from the analogy displayed in its general features to those of the stronger-growing and larger-foliaged species of that genus. However this may be, there can now no longer be a doubt of its incorrectness, and the consequent necessity of changing its name. Seeds were imported from the Swan River Colony and distributed by Capt. Mangles a few years since; and Mr. Young, of the Epsom Nursery, was fortunate enough to raise a number of specimens which have since been multiplied by cuttings, and distributed amongst the principal metropolitan establishments. The original

plant flowered profusely with Mr. Young for the first time last March. Although flowers have never been disclosed before the present year, the prodigality of their production, in every case we have witnessed, justify us in considering it as a free-flowering and highly ornamental species. At Ealing Park, Mr. Robertson had a number of small plants just raised from cuttings, completely laden with blossoms. These had been kept in a warm house; and we have no doubt that the flowering, and indeed the health and vigorous growth of most New Holland plants, will always be vastly improved by the application of a little additional warmth in the early spring months when the shoots are tender. The name of the genus is a combination of *two* Greek words, *gemini*, the belly, and *lobos*, a pod, alluding to the distension of the legume. The marginal spines of the leaf have suggested the specific term.—*Paxton's Magazine of Botany.*

Garden Memoranda.

Horticultural Society's Garden, Turnham Green.—The Orchidaceous-house here is undergoing repair, and at the same time considerable alteration. In addition to the hot-water pipes, which run round the house under the front and back shelves, by which it has hitherto been warmed, the bed under the plants in the centre is about to be heated by hot water in open iron tanks, constructed by Burbidge and Healy. This is to be effected by means of a flow and return, inclosed in a hollow chamber covered in with slates, on which the plants are to be placed. These tanks are to be set on brick supports, about two feet from the bottom of the chamber, which is 3½ feet deep, and are to be heated by one of Burbidge and Healy's new boilers. The hot water will be conducted from the boiler to the tanks by means of one-inch pipes passing under the pathway into the bed. In order that the house may be steamed occasionally, small openings will be made in the sides of the chamber and furnished with sliding lids, to be opened or shut as required. All the rain which falls upon the roof will be collected in a large slate cistern, placed at one end of the bed which occupies the centre of the house. It measures 5 feet 9 inches in length, 3½ feet in width, and the same in depth. The curvilinear stove was gay with the several species of Achimenes, among which was the new one, A. picta, which, independently of its beautiful blossoms, is richly clothed with a finely variegated foliage, which the other sorts do not possess. In this house was also in flower the yellow variety of Gloriosa superba, an old and well-known plant, but one which is seldom seen in bloom; Lælia superbiens is growing here on a large block in great luxuriance, and is again throwing up several flower-stems. The specimen of Aristolochia gigas trained along the roof has produced its singularly large concave blossoms in great abundance through the whole summer months, and is still in fine bloom. It does not succeed well when grown in a pot; but, when planted out in the border of a stove, it thrives and flowers profusely with little care, speedily spreading over a large space. In the house, which was formerly a Pine-stove, but which has lately been much altered, the plants are looking well, the Orchidaceæ, on charred blocks, indicating by the healthy green of their foliage that they like the situation. On the front shelf was a plant of Clerodendron fallax, producing a head of flowers of brilliant scarlet. The plants in the large conservatory are looking well; it is in spring, however, that this house presents the gayest appearance, when the Acacias and other leguminous plants are in bloom. The front shelves are at present decorated with several of the new varieties of Fuchsia, which were displaying an abundance of showy blossoms. Trained up the south side of the house was a plant of Centrosema splendens in flower—an exceedingly handsome scarlet climber: it is better known in gardens under the name of Kennedya splendens. The sweet-scented Mandevilla suaveolens was also twining here in "Nature's careless grace," and expanding numerous clusters of snow-white blossoms. Along with these was Bignonia jasminoides, which is one of our prettiest autumn-flowering climbers; and in the same collection, turned out into the bed, was a large specimen of Cestrum aurantiacum, producing fine panicles of showy orange flowers. This valuable addition to the conservatory was contributed by Mr. Skinner, who sent it from Guatemala, a year or two ago; and, finally, a specimen of Hedychium Gardnerianum, planted out in the bed, was also bearing a spike of rich yellow flowers with prominent scarlet stamens. The late warm summer has brought many of the autumn Pears into use earlier than usual, and a large quantity of fine fruit is already in the fruit-room. The samples of Beurré Diel, both from the wall and from dwarfs, are exceedingly handsome. Those from standards are not so large, owing to the late dry summer. Specimens of Beurré Rance from the wall are unusually large and fine. We measured one which was 6 inches in length without the stalk, and fully 10½ inches in circumference. The floor of the fruit-room, which was made of concrete in the first instance, although it perfectly answered the purpose as regards dryness, had become very uneven. It has now been overlaid with Portland cement mixed with three or four parts of sharp sand. This has been done a week; and the cement was becoming exceedingly hard on the surface, and of the colour of Portland stone, although it sets much slower than the other cements.

Royal Botanic Garden, Kew, Sept. 25.—The two Fourcroyas, mentioned previously, p. 540, are now in blossom—at least that part of them which is within the stove. Several feet of the panicle, which have been allowed a passage through the roof, are still only in bud. There is only 13 inches difference in the height of the two (and they have not yet done growing); the tallest is 35 ft. 6 in. from the ground to the top of the panicle.

Miscellaneous.

China.—Advices have reached the Horticultural Society from Mr. Fortune, dated May 10. He was at that time residing in a Chinese temple, called Tsze Tung, in the Ningpo district, in the midst of the Green Tea cultivation. Hundreds of Chinese were busy gathering the leaves of the shrub, which covers the sides of the hills. This part of the country has proved by far the richest place for plants and scenery which Mr. Fortune had yet visited, many of the plants which had been previously only seen in gardens, being there wild in the woods and hedges. He had succeeded in reaching Shanghae, in the Moutan season, and found hundreds of gardens there filled with this beautiful flower. Some capital Azaleas had also fallen in his way.

Destruction of the Gooseberry Caterpillar by Salt.—To destroy the green worm, as also the small orange-coloured aphides, which often injure the bushes and destroy the fruit, we sprinkle the plants with salt and water early in the spring, before the leaves are developed; the mixture may then be made so strong as to whiten the branches, without affecting the future crop. Should the leaves or buds be in part expanded, the brine should be greatly reduced, say one quart of salt to about eight gallons of soft water, applied over the bushes from the rose of a watering-pot.—*Hovey's Magazine of Horticulture.*

Monstrous Grape.—There has been lately produced at Stover, in Devonshire, one of the seats of the Duke of Somerset, a berry of a Black Hamburgh Grape, which measured 5 inches in circumference. It was much flattened, and even depressed, at the stalk and opposite end, and, being furrowed, presented somewhat the appearance of a Tomato. It contained 10 seeds apparently perfect.

New Variety of Grapes.—M. Lenoir, a recent French writer on Vines says, that "a seedling Vine raised by M. Van Mons, at Brussels, produces fruit as large as a Green-gage Plum, which, at the latest, ripens in the first fortnight of August, and never fails. Its qualities are no less remarkable, as it is both solid and sweet."—*Journal of Science and Art*, vol. xxvii. p. 229.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

It may be useful for many to know that one of the finest winter stove plants, Gesnera zebrina, has yielded to a greenhouse treatment all the year round. It was allowed, for want of better convenience, to start of its own accord, which it did early in summer. The cold this time last year put a stop to its growth, and it lived in the greenhouse through last winter along with Pelargoniums, Fuchsias, &c., without any injury to its foliage; it began to grow again in spring, and flowered for a long time last summer. As this plant is a general favourite in drawing-rooms, &c., for which its tubers and succulent foliage make a provision for hard usage, a few of them might be thus treated in every place where such plants are in demand; and not only so, but the experiment opens a field which may extend farther than many of us are aware of. There is no variation in the treatment of the stove worth noticing this week.

Conservatory.—The general treatment of this house also will be uniform for some time to come. There are two varieties of Bignonia jasminoides in cultivation, one of which is a very shy bloomer and ought to be discarded; the other is the finest of our hardy greenhouse climbers—a peerless beauty as Deronian calls it. Cuttings of the latter, struck any time before the end of October—and they root as free as willows—will blossom all through next summer in very small pots. At the risk of being thought tiresome I shall once more notice the lovely Mandevilla suaveolens: it has been in flower here all this autumn against a wall in the open air, and looks more healthy than plants of it in-doors; this climber is one of the best to train as a specimen over a wire trellis; and as it requires to be pruned closely every year, after flowering, it may be kept in a dry shed along with Fuchsias, Myrtles, &c., through the winter, and either forced in spring, or allowed to break of its own accord in May; long shoots of it, two or three years old, will root as freely as a Grape Vine, without tongueing, and thus a large specimen may be got from an old plant in one season. If the shoots will allow put two or three coils in the pot, as Mr. Mearns would do with a Vine shoot, and you will have more roots to sustain the specimen.

Pits, Frames, &c.—It is now time to put young Gardenias, Neriums, and Orange trees into their winter quarters. A cold pit, from which the frost can be excluded, is the best place for them: as they are always kept in the smallest pots into which their roots can be got, and force best when thus under-potted, it often happens that their roots perish during winter; to prevent this, it is a good plan to turn them out of the pots now, and plunge the balls in a thin layer of light earth during their rest; but as Gardenias will flourish in peat only, they should be plunged in it. Besides these, there are scores of half-hardy delicate plants, which will keep better in the same way through the winter than in pots, as their roots are thus in a uniform state; and if damp appears at any time, a little dry compost scattered over the surface will prevent it. A slight hotbed of half-spent dung is a good place to begin to force China and Perpetual Roses about the beginning of October; the lights may be left off all day at first, unless it rains.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

Those who have tender greenhouse shrubs, such as Heaths, Leschenaultias, &c., planted out in beds, must now begin to think of getting them housed for the winter. It is surprising how fast plants grow when planted out, but it requires great care and attention in their management after they are taken up, or they are very liable to damp off during the dark months of winter. Some plants of Leschenaultia planted out in June last, at which time they were very small, are now strong plants which will require number 12 sized pots when they are taken up. In removing them, the ball of earth must be so much reduced in size as to admit of an inch or two of turfy soil being placed all round it when potted. This is essentially necessary, and a secret upon which their future success in a great measure depends; for the plants being provided with fresh and healthy soil to work into, they sustain little or no check after the removal. After they are potted, place them in a close frame on a north aspect; sprinkle the plants lightly every morning, and keep the frame close during the middle of the day, but they may have plenty of air during the night. When they have recovered the check, place them in a sunny situation, to harden the tissue of the plant, but do not permit them to flag, or the foliage will become brown and rusty.

Bulbs.—Many of the early kinds of Tulips and Narcissus are now beginning to grow; and therefore, to keep them out of the ground any longer will injure them. As, however, it is impossible to plant them permanently until the autumn plants are removed from the beds, it will be found a good plan to place them upon an inch or two of finely-sifted leaf-mould and sand, and to cover them several inches deep with old tan or leaf-mould. In this situation they will make root, and may be removed to their proper situations with the soil adhering to their roots as soon as the beds are ready for their reception. The same observations apply to all kinds of bulbs or tuberous-rooted plants that are desired for early spring decoration, as, for instance, Anemones, Crocuses, Snowdrops, Hyacinths, Scilla, Crown Imperials, &c. &c.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Continue, every favourable opportunity, to pot off Carnation layers: let the grass or leaves be dry, for when wet with either rain or dew, the soil, which will sometimes get in the axils of the leaves (however carefully they may be handled) is difficult to be removed, and if not, will prove detrimental to the plant during winter. The layers must be put in a close frame for a few days till they have again struck root. *Tulips.*—Seedling bulbs when very small are best in the ground, and small offsets of choice sorts had also better be planted. *Auriculas.*—Any offsets which may not have been ready earlier in the season must now be removed, planting carefully round the side of a quart pot; water to settle the soil to the roots, and place in a situation free from drip or heavy rain. *Pansies.*—Continue to make the beds for next year's blooming, and propagate by slips all that it is desirable to increase. *Polyanthuses.*—Seedlings may still be pricked out to get established before winter. Compost heaps should be turned, and all insects carefully picked; a small quantity of quick-lime will prove beneficial to the decayed turf intended for Tulips.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pinery.—Ripening fruit should be kept in a dry, warm atmosphere, to give it flavour. The swelling fruit should have a warm, moist atmosphere; when water is required it should be given more sparingly, since evaporation goes on much slower at this season, and the soil, receiving more water than the plant can take up, becomes soured, causing the fruit to ripen without flavour. It is proper after this season to let crowns and suckers, after being trimmed, lay upon the kerb of one of the pits to dry, for a day or two before planting. Endeavour to keep the linings (where in use) dry, as rain causes the heat to decline suddenly, and consequently causes much labour in turning and renewing.

Vinery.—The Grapes for winter use demand constant attention, to prevent their being injured by damp. As early in the morning as convenient, let a slight fire be made; and as soon as it begins to tell upon the thermometer, open the top ventilators, to let the damp pass off. Towards evening the heat in the flues or pipes will have declined, and the house may be closed, to keep out the damp night air. If the Grapes are covered with paper bags, the bags should be removed occasionally, to examine the berries, as, if one berry begins to decay, it will soon infect the whole bunch, if not removed. Where means have not been taken to protect the outside borders from wet, no time should now be lost, particularly with the borders of those houses intended to be forced. Dry Fern is an excellent material for keeping borders dry and warm. It must be laid on thickly, in layers, beginning at the front of the border. The whole should be covered with a thin layer of good straw, and fastened down with ropes and pins, as a thatcher would fasten the thatch of his stacks.

Peach-house.—If the directions already given for the early house have been followed, nothing more will be required than to keep the trees as cool as possible. The second house will soon be ready to be put in the same state of order as the first, and from the time that all preparations are completed in these houses, they may be made exceedingly useful for keeping plants of various kinds in, till the forcing commences. Care should, however, be taken not to bring into them any plant that is not perfectly free from insects.

Figs.—The trees that are still bearing should have slight waterings, to assist them to perfect their fruit; but trees having no fruit likely to come to perfection, and whose leaves are fading, should be kept dry and cool, to induce a state of early rest. Plants in pots should not be kept growing longer, or they will not be in a fit state for forcing early.

Melons.—Give scarcely any water after this. Continue to maintain a warm, dry atmosphere, to give flavour to the fruit.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Cucumbers.—To prolong the season of fine crisp Cucumbers the plants must be kept clean and healthy by giving them plenty of top and bottom heat. This can be easily effected in frames, if the bed has been perforated with pipes; but the disadvantage of frames, when contrasted with good close pits, is, that in the one case great care must be taken to prevent any rank steam from the dung entering from the lining, while in the other there can be no danger in using the fermenting material as fresh as you can get it. The chief difficulty is the securing abundance of it. If that can be obtained, and you have some nice strong plants in pots, a fresh bed might now be made, to produce in the earlier months of winter; but without abundance of fermenting material it would be folly to attempt it. Those who grow them in hot-water pits will now have their winter plants in good order. *Manure.*—Take every opportunity of converting all refuse vegetable substances, clearings of roads, cleanings of sheds, &c., into rich dressing for the garden, by watering with the liquid that distils from Melon-grounds, dung-hills, &c. I have tried a number of the new manures upon a small scale, and though useful as auxiliaries, I find that there is nothing preferable to old hot-bed dung, and the decomposing heap of those substances that can be collected in a garden, for the production of good, medium-sized, high-flavoured vegetables. Weak solutions of guano, superphosphate of lime, &c., frequently repeated, were found very serviceable to strong growing plants in pots, Cucumbers in boxes, &c., but the same apparent benefit was not the consequence of their application to crops in the open garden: though it is right to state that Cauliflower was considerably improved, especially by guano, and that Celery was rendered of a deeper green colour by the application of nitrate of soda; but, in size and flavour was not anything superior to that grown in the usual manner. However concentrated the strength of these new manures, it must be evident that whatever their chemical influence, they can affect the mechanical texture of the soil but little, and hence, so far as rendering loose soils more retentive, and stiff soils more open, the old (now attempted to be discarded) system of manuring must ever maintain a great superiority. It is true, a similar mechanical effect might be produced by a proper application of lime, chalk, marl, or in extreme cases, of clay or sand; but these operations cost both trouble and expense. It is a pleasant thing for a gardener to get rid of all his dung-pits and rubbishy-looking linings, but he will act wisely if he makes the most of an old assistant before he is well supplied with a new one, as, however anxious he may be to follow in the wake of new improvements, he may find that when he has rendered himself deficient in muck, there may be no striking desire manifested for spending good gold on guano, &c., nor yet in furnishing him with the means of producing early vegetables without the assistance of fermenting matter. *Routine.*—Tie up Lettuces and Endive, earth up Celery, and gather fruit in fine weather. Encourage the ripening of the wood of Peach-trees, &c., by exposure and shortening the shoots. Remove everything offensive in the way of decaying Bean-stalks, Pea-haulm, ran Lettuces and Endive, and weeds, wherever they appear. Give everything a fresh and neat appearance, by frequently stirring the soil, and by sweeping and rolling the walks.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—Now is the time to fix upon what trees should be taken out, and what sorts should be planted to improve the scenery and enhance the value of Old Woods.

Coppice.—Attend to the directions given in last week's Calendar. *Prepare* ground for planting, and fill up vacant spaces; taking care to select the most profitable kinds of trees, shrubs, &c. for the purpose.

Young Plantations.—Where new ones are about to be made, I would strongly recommend planting a sufficient number and variety of plants for permanent undergrowth, at the first planting, where shelter or blinds are desirable, as they will have a better chance to establish themselves than when planted at a future time; take care, however, to head them off at different heights, in order to keep them low and bushy, and to prevent them from injuring the permanent trees; this method is equal to thinning in their first stages of growth. The beneficial effects of it may be seen in Dr. Thackeray's plantations at Norquis, where some Beeches have been headed off, and Spruce Firs broken off. In addition to the kinds specified in last Calendar as suitable for this purpose, I would plant plenty of Hollies, some Yews, and various other choice evergreen and deciduous shrubs, especially near the sides of rides and walks.

Hedge-rows, &c.—Refer to late Calendars.—*W. B.*

VII.—COTTAGERS' GARDENS.

As we may expect cold weather soon, any plants turned out into the border that are worth preserving, and that are likely to be injured by frost, had better be lifted and potted without delay. As soon as scarlet Pelargoniums become unsightly they may be taken up, the soil shaken from their roots, the stems shortened back a little, and then put into small pots, in which they can remain through the winter. Place them in a dry situation, cool, but secure from frost, and give them little or no water. I have known them to be successfully preserved over winter hung up by the roots in a dry cellar. Plants in pots in the window should be sparingly watered, and after this time it should be given in the morning. This autumn has been very favourable for all gardening operations. Advantage should be taken of fine weather like the present for digging up the Potatoes where they are ready for lifting. After they are raised let all weeds, haulm, &c., be cleared away to the manure heap, for upon its accumulations the crops for next year greatly depend. Lettuces sown in August will now be in good condition for transplanting. This should be done in rows about nine inches apart, and let the plants stand about six inches apart in the row; they like a rich, light, and, for winter, rather dry soil; the situation should be a warm border if possible. When these, and late Cauliflower plants are put in, little more will be needed in the planting way for some time. Keep a few Endive plants blanched, by inverting a flower-pot over them, closing up the hole in the bottom of the pot, in order to prevent wet and light from entering. Continue to gather fruit as it becomes ripe, taking particular care to prevent its being bruised or injured in any way; the slightest bruise upon the fruit, even although not visible on the outside at the time, will ultimately occasion premature decay. Grapes ripening on walls should be protected, if frosty nights are likely to occur.—*J. McH.*

State of the Weather near London for the week ending Sept. 20, 1845, as observed at the Horticultural Garden, Chiswick.

Sept.	Moon's Age.	Barometer. Max.	Min.	Thermometer. Max.	Min.	Mean.	Wind.	Rain.

Notices to Correspondents.

To Correspondents.—*Lover of Accuracy.*—We have never received either of the inquiries to which you refer. Rely upon it no question is ever unanswered more than a week, and this only happens when inquiries do not reach us before Friday, or require a great deal of consideration.

Apple-tree.—*A Lady.*—Your trees, 6 yrs. old when transplanted two years ago into poor soil, and which are now weak and moss-grown, will be improved by a good dressing of farm-yard manure dug in before spring. The trees should be moderately pruned back as soon as the leaves have fallen; and if they are occasionally powdered over with lime, or washed with lime-water, it will tend to prevent the growth of Moss.‖

Asparagus.—*E. G. L.*—Potter's Guano may be applied at the rate of half-a-pound per square yard to Asparagus-beds. It should be well diluted in water, and applied in portions weekly during the early part of summer, commencing immediately the cutting is over. Salt, at the rate of 1 lb. per square yard, may be applied at once in spring. Other manures may be employed along with it.‖

Bees.—*A Young Apiarian.*—Your bees might survive the winter by feeding, but for the want of brood-bread, an essential thing seldom thought of, they must be weak as the spring advances; therefore the best way is to unite them to those in the common hive thus:—In the evening fumigate both parties; take the queen from the weakest hive and destroy her; mix the bees, and let them ascend into the straw-hive, impressing them next day to cement their friendship.—*J. Wighton.*

Books.—*H.*—Mackintosh's "Practical Gardener," Roberts "On the Vine," Mills "On the Cucumber," Lindley's "Theory of Horticulture," Knight's "Physiological Papers."‡

Carnations.—*W. O.*—Your scarlet bizarre more resembles Twitchett's Don John than any variety with which we are acquainted.*

Exportations.—*J. C.*—If you pack your cuttings very tightly in a box of sphagnum, and nail them down so that they cannot be opened, they will travel pretty well. The best way, however, is to plant them in Ward's cases, if you do not regard the expense and can find a good conveyance.—*G. L. C. F.*—We presume the best way to take Apples and Pears to India—by the overland route, of course—would be in a box of dry sand. We can hardly anticipate the possibility of sending them round by sea! We have indeed seen such fruits arrive from China in tin cases, and still green; but they were quite spoiled, and worthless.

Flower-Garden.—*A. W. G. B.*—We fear that there is no possibility of making a garden gay in autumn, without pot-culture; for where is a substitute to be found for scarlet and other Pelargoniums, Verbenas, Petunias, &c.? If you rely upon Annuals you will be disappointed; if upon herbaceous plants, few are handsome enough for the purpose. Possibly some of your beds may be filled with the following:—Campanula grandis, Convolvulus lanuginosus, Double Pinks, Delphinium grandiflorum (double), Statice tatarica, S. spatulini, and Pseudo-Armeria, Double Poppy Anemone, Potentilla Russelliana, Œnothera speciosa and macrocarpa, Heartsease, Gladiolus psittacinus, Double Stocksts, Lathyrus grandiflorus, Double Scarlet Lychnis, Radbeckia serotina and hirta, Phlox Drummondii and procumbens, Monarda didyma, Stenactis speciosa, Aquilegia glandulosa, and Gentianas of sorts.¶

Heating.—*A. M.*—A small boiler, troughs, and some 3-inch pipe will enable you to heat your pit better than with dung.—*A. B.*—You may keep frost out of such a house as you describe by means of a good Arnott stove placed in the middle; it should be a third-size above the small ones, and furnished with a hopper. But it would be far better to heat it with hot water. We never give you prices—for that you must consult the dealers.—If you use an Arnott stove you must recollect that it requires *very careful management.*—*A Subscriber.*—Do not employ steam for heating. It is very expensive and inconvenient. If you do, you will be glad to pull your apparatus down again. Why not adapt hot-water pipes to your still; or rather, why not sell your copper still, and lay the money out in heating the house with hot water.—*Amateur.*—You may certainly grow plants in the manner you propose; but you must have some means of shutting off the hot water when you do not want it, or you will have too much in summer. Three inch pipes will do very well. Melons may be grown in such a place, provided you can warm the soil a little without drying it.

Hollyhocks.—*D. O.*—The Hollyhock is little more than a biennial, and frequently dies suddenly, if sown too early in the first season, or if allowed to remain long in the seed-bed before transplanting; therefore the best way to keep them in health is not to sow them before June, and, when large enough, to transplant them singly where they are to remain and flower in the following season; afterwards cut them down as soon as they have done flowering, and remove them to a fresh situation, where the ground has been well manured, before winter. By continuing this treatment you may keep the same variety for years.¶

Insects.—Our correspondents inquiring about insects will oblige us by addressing their letters hereafter to John Curtis, Esq., Olive-cottage, Hayes, near Uxbridge, Middlesex.—*Cotton Blight.*—You will find an article upon the cotton or American blight, at page 116, of the *Chronicle* for this year. *R.*—*A Lady Subscriber.*—The gardener is right; the wasps are females, and will live through the winter. *R.*—*North Esk.*—The insects transmitted with the Melon-leaf are a species of thrips, and we are unable to suggest any remedy at present beyond those already published. *R.*

Larches.—*A. B.*—There are two very dwarf kinds of Larch, one a variety of the common Larch (Larix europea), which seldom grows more than two or three feet in height; the other is Larix leptolepis, a Japan species, of about the same stature.¶

Lawns.—*A Subscriber.*—If your Grass is quite killed, you had better procure some fresh cow-dung and strong loam mixed in equal proportions, and put a good covering of it over the old turf (without moving it), and relay it with fresh turf; it should have been well watered two or three times during the very dry weather; this would have prevented it from being killed, and is much the cheapest way in the end.¶

Manures.—*J. N. C.*—The mud from your water-course must be very strong. We should water it with a solution of sulphate of iron to destroy the smell. It might then be applied advantageously to your borders, which, if they are light and sandy, would be much benefited by it. In order to ascertain whether it is too strong, sow a little Mustard seed on a small quantity of it. If the plants come up quickly, and are of a deep green colour, it is fit for anything, and need not be feared.—*Southdon.*—Sea-kale will be benefited by being dressed with salt like Asparagus. It should be applied just when the plants begin to grow in spring.‡

Names of Fruits.—*Worcester.*—5, Flat Nonpareil; 10, King of the Pippins; 17, Sops of Wine; 26, Ribston Pippin, 27, Minchall Crab; 29, Ribston Pippin. Pears: 11, Seckle; 12, Ambrosia; 18, Gilout Morceau; 19, appears to be Williams's Bon Chrétien; 20, Passe Colmar.‖—*J. P. M.*—The disputed Pear is the Brown Beurré.‖—*H. M. H.*—Your Apples ascertained in their present immature state are,—No. 3, Lamb Abbey Pearmain; 5, Keswick Codlin; 9, Blenheim Pippin; 10, Yorkshire Greening; 13, Court of Wick.‖—*W. R. H.*—No. 1, Blenheim Pippin; 2, Nonesuch; 3, Norfolk Beaufin; 4, Chaumontel; 5, Seckel.‖—*Phœbe.*—Supreme Crab.‖—*J. H. L.*—2, Blenheim Pippin; 3, Kerry Pippin; 4, Hollandbury; 7, Keswick Codlin; 8, Northern Greening; 9, Margil.‖—*Worcester.*—6, Flat Nonpareil; 13, King of the Pippins; 11, Seckle.‖

Names of Plants.—*Hortus Siccus.*—No. 1, Coronopus didyma; 2, Peltaria alliacea; 3, Helosciadum inundatum; 4, Spergula nodosa; 5, Bartsia Odontites; 6, Ranunculus aquatiles; 7, Ranunculus hederaceus.‡—*H. C.*—Tussilago nutans, now called Leria nutans, is neither a Portuguese plant nor a succulent, but a native of Mexico. It has no English name. It is a purple-flowered plant of no beauty—not worth growing for ornament.—*Z. Long.*—Elæagnus hortensis.—*L.*—Your Fern seems to be a seedling of Asplenium rhizophorum.—*A. C.*—A Cuscuta, probably brought in with the soil.—*A Regular Subscriber.*—The productions which you have forwarded on the roots of a species of Zichya are not, as you suppose, Fungi, but of the same nature as the bodies which are so common on the roots of leguminous plants. The nature of these bodies is not at present well understood, but M. Desmazières has prepared a Memoir on the subject, illustrated by beautiful drawings, the publication of which has unfortunately been delayed from an attack of the eyes, which has prevented the completion of his observations. These bodies are produced very shortly after the germination of the seeds; and if the gradual development be traced, as it has been by ourselves, it will be found that they arise from the cellular tissue, though generally having one or more branches from the vascular bundles at their base. The contents of the cells at a certain stage of growth become blue from iodine. At a later stage, the cells are filled with short straight, or forked bodies, first observed by M. Desmazières. In your Zichya, the excrescences are very large; but, as far as can be judged from dry specimens, they are of the same nature. It is not known what the function of these bodies is, but it is probable that, in very dry weather, they may be reservoirs of nutriment. The contents of the bodies soon become pulpy, and the bodies themselves eventually burst. Your plant has perished probably from some other cause; and, if we may judge from the disgusting smell of the specimen, the cause of death has been the application of too strong manure. *M. J. B.*

Peaches.—*B. O. D.*—In this dry season, Peaches have been apt to drop prematurely, especially late sorts. The late Admirable has not attained the perfection it usually does in moist summers. That which you have for the Noblesse is perhaps the late Admirable.‖

Pelargonium.—*Acland.*—A list of the best Pelargoniums for forcing appeared in last year's vol., p. 28.*

Pine-apples.—*A Subscriber.*—All we knew of Mr. Mills's pits has been stated. One plant grew under the middle of each light. Upon looking again at the account of his operations, given at p. 610, we find that the pits are said to be *three* feet wide; this is, of course, a misprint, and should be *four* feet. A common 3-light box measures about 11 feet by 5.

Planting.—*J. M. T.*—Transplant your evergreens in the very beginning of November; they like moderately light loamy soil, and require no manure. If you grow them too fast they will not ripen their wood, and then the winter will kill them back.—*S. N.*—Tall Yews early in the winter. If your Roses are tender, as many of the Bourbons and Tea-scented kinds are, you had better not plant them out before spring. All the varieties of R. sempervirens are tolerably hardy; we are unacquainted with the Triomphe de Rollwyller. Verbascum phœnicœum is quite hardy.

Strawberries.—*Delta.*—Runners do no good to the parents from which they spring, but the contrary, and are better stopped. Never cut off leaves from Strawberry-beds after fruiting; it is a very bad practice. People reason—no, not reason, but say—that as they have good crops in spite of cutting off the leaves, the operation must be a good one. They do not inquire how much better the crop would have been if they had left the leaves alone. We should think that Pears would grow very well against your walls, if they are hardy sorts, such as the Beurré Rance, Passe Colmar, Easter Beurré, Marie Louise, Napoleon, Glout Morceau, Diel, &c. Why not try the experiment with one tree first? If they will grow one year they will do. The great baking Pear called Uvedale's St. Germain, would be almost sure to succeed, and so would Monsieur le Curé. What is a horse-shoe espalier? Cold, damp walls will do no harm to Apples and Pears, but they certainly will injure Plums and such tender trees.

Tobacco.—*W. T. B.*—It is unlawful to plant Tobacco except in any physic garden of either University, or in any other private garden, for physic or chirurgery only; and in those places the quantity so planted must not exceed half a pole. Heavy penalties are also incurred by manufacturing Tobacco without attending to the Excise Regulations on the subject.—*W.*

Transformations.—*A. W.*—We are far from saying that Potentillas will not change into Strawberries. The only difference between them is, that one has a dry and the other a succulent receptacle. In fact, what Linnæus called Fragaria sterilis is now called Potentilla fragaria. What you have sent is P. nepalensis. We hope we are not doing wrong in giving the public the benefit, now and then, of your clever letters.—*A. M. S.*—It is not impossible that a warted Gourd should produce something like a Vegetable Marrow; but it is rather improbable. We should fear there has been some mistake. We could find no Rose-leaves in the letter.

Vines.—*S. S.*—The fruit being cut, it will be proper to give all possible air, with moderate heat, but gradually diminishing the latter till the leaves drop. The Vines may then be pruned and turned out. Provided the wood is sufficiently matured they will not suffer from cold, and may remain out till February, if you only commence forcing in March.‖

Miscellaneous.—*G.'s* note is sent to Mr. Paxton.—*Micklewell.*—Let your Iris chinensis remain as it is. Brachystelma is an ugly plant, allied to Stapelia. Keep it dry and warm in the winter. Gladiolus fragrans is very sweet, and violet-coloured. Ixia maculata has dark spots at the base of the petals. It is evident that your Cape bulbs are wrong named.—*An Old Subscriber.*—We never heard of an objection to a purchaser picking such bulbs as he prefers. If any "old gentleman" refuses to allow it, his customers should go to the next shop.—*William.*—Your house is so very narrow, that slight rafters will do; and we think 5 by 3 inches quite strong enough. By all means hinge your front lights if you wish it. Sliding sashes are, however, most convenient, and least liable to get out of order.—*Z.* is answered in the "Calendar of Operations" for this week.‡—*H.*—Bougainvillea spectabilis is a charming thing, with heads of Lilac flowers resembling Hops. It is now in flower in the great Conservatory at Chatsworth; but we never saw it in that state before, it being apparently difficult to flower. Any nurseryman may procure it of his London correspondents, if he will give himself a little trouble in inquiring. It may be struck from cuttings without difficulty. If you plant it out give it plenty of light and warmth in the summer, and keep it cool in winter.—*C. C.* must give his name and address. We cannot insert statements of facts without their being confidentially authenticated by the writer's name and address.—*T. O. R.*—It is said that Indigo is a cure for wasps' stings.‡—*W. H. F. C.*—The cause of your Mignionette withering in small patches and dying down, probably arises from damp at the root; keeping the plants thin and open will possibly remedy the evil.‡—*H. H.*—The dry season is no doubt the cause of your Raspberries not having made young wood this year. You had better cut out the old wood at the usual time.‡—*W. C.*—Ipomœa ficifolia is not one of the best conservatory climbers, but it is a very handsome species. We do not expect that Stephanotus floribundus will succeed in a house where the temperature is only 50° ‡—*N. T. B.*—You may commence to force your Vines about the end of November, but you must take care that the outside border is kept warm in winter.‡—*Octavia.*—A cellar is a good place to store up Carrots and Beet-root, if it is dry. It is yet rather early to introduce plants into heat for winter flowering. If you watch our Weekly Calendar of Operations you will obtain full information on all such points.‡

SEEDLING FLOWERS.

Dahlias.—*M. J.*—Neither of your seedlings are equal to similar sorts in cultivation. No. 1 is too small and undecided in colour; in No. 2 the centre opens irregularly, and the flower wants depth.*—*Sunbeam.*—Nothing was left but the centre of your flower when it reached us; from the quantity of loose petals in the box, we imagine it to be rather flat, and the centre shows too many flat, pointed, and unbloomed petals.*—*D. D.*—Your seedling is decidedly worth cultivating; the tip is fine, and distinct in colour; the petals in the centre are rather too upright.*

Fuchsias.—*J. L. V.*—Your seedling with a light tube and sepals tinged with green, having a pale rosy-purple corolla, with deep-green foliage, is the largest flower of the light class we have seen; but the colours appear to be rather too faint.*—*C. B.*—There is nothing remarkable in your seedlings; the peculiarity you point out is not a desirable one.*—*W. J. E.*—Your seedling, having a very light tube and sepals, with green terminations, and the crimson corolla having a purple tinge, is a distinct and handsome flower, of a medium size.*—*T. F.*—The lighter seedling of the two sent is not worth keeping; the other variety is large, bright, and rich in colour, and though somewhat like others in cultivation, is equal to any of its class.*—*Y. and Co.*—Your seedling named Alicia is a plant of handsome growth, and the flowers, which are produced in great abundance, agree with the following description:—Tube and sepals delicate flesh-colour, the latter having green points; corolla stout, of a deep blood-colour; flowers of a medium size.*

Petunias.—*T. J.*—It should be stated with regard to this flower, whether the plants have been grown in pots, subjected to greenhouse cultivation, or grown in the open border, from the extreme delicacy of your specimens the former appears to have been their mode of growth; they differ from all others we have seen in their extreme delicacy of texture, and the fineness of the pencilling in and around the throat. No. 4, named Elegans, combines fine form with great neatness; 2 and 5 are very pretty, having Violet pencillings on a white ground; 1 is large and wants flatness; it is also too much indented on the outline; 6 is not uncommon.*—*R.S.S.*—Your pencilled seedling No. 1 is a very pretty flower of good form, and firm in texture. No. 3 is rather small, brilliant in colour, but not improved by being mottled; that quality wants decision.*

Trunbergias.—*Joseph Fryer.*—We do not perceive any difference in your blooms from those of T. aurantiaca and alata. With regard to the plants not being subject to red spider, we doubt the fact, judging from the specimens which we have received.‡

GUANO for SALE, in Bags of 1 cwt. each, just landed; with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the Manure as shall fully develop its productive powers. To secure to buyers these indispensable requisites, with each purchase will be given a warranted chemical analysis of quality, and also a copy of the recently-published Pamphlet, "Practical Instructions for using Guano as a Manure, illustrated by Practical Results."

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 24 and 25, Billiter-street, or delivered within any reasonable distance at a trifling additional cost. Apply to JAMES CLARK, 24, Billiter-street.

WHEAT-SOWING.

FREDERICK BRAIN begs to call the attention of the Agricultural world to his GUANO MANURE, prepared expressly for Wheat crops: it abounds in all the ingredients that are necessary for a good grain crop. He particularly solicits persons who found the Foreign Guano a failure last season to give his a trial, it being much more powerful, and free from adulteration, so justly complained of in the Foreign by Agriculturists, as well as by all the leading Agricultural Journals.

Testimonial to Brain's Guano Manure.—"5 A, Hawley Road, Kentish Town, London, Aug. 15, 1844.—This is to certify that we have subjected Brain's Guano to a most patient and rigorous analysis, and find it contains all the necessary constituents of a good manure, and is well calculated to give fertility to a soil which is either naturally barren, or has been exhausted by over-cropping, by supplying the land with those substances which are absolutely requisite to a healthy vegetation: (it is not adulterated, and can always be depended on, being of uniform composition.)—(Signed) JOHN MITCHELL and FREDERICK FIELD, Analytical Chemists, of the Royal Polytechnic Institution, London."

Also, BRAIN'S highly-concentrated LIQUID GUANO, for Grass Lands, Gardens, Shrubberies, Hothouses, and Conservatories, price 1*s.* 9*d.* per quart bottle, with full directions for use, (enough for 80 gallons of Liquid Manure), to be had of most respectable Florists, Seedsmen, and Chemists in town and country.

Works, Thomas-st., Duke-st., Stamford-st., Blackfriars-road.

FARMERS' CLUBS.

Sept. 30—Chepstow. | Oct. 5—Collumpton.
Oct. 2—Harleston. | Oct. 8—Abergavenny.
Oct. 9—Monmouth.

WE have read with an interest, which has doubtless been shared by the great majority of our subscribers, the accounts of the agricultural improvements effected by Mr. Mechi, the spirited proprietor of Tiptree Farm, and we heartily hope they may fully answer the expectations of their liberal and enlightened promoter*. Some THEORETICAL VIEWS ON DRAINAGE are proposed by Mr. Mechi in our Number for August 17, avowedly for the purpose of inviting discussion; and therefore we have no scruple in submitting our doubts as to the correctness of some of them. The point particularly alluded to is the statement at p. 562, in the middle column. Mr. Mechi's proposition is as follows:—"The surface of the drains should nearly equal the surface to be drained; so that if the surface to be drained were nine square feet, the sides and top of the drain should present an area of nine superficial feet."

This proposition appears to be stated in much too general a manner, for we do not perceive that any necessary connection can exist between the area to be drained, and the dimensions of the drain by which such area shall be effectually freed from the stagnation of surface-water; on the contrary, it appears to be very evident that the proper extent of porous surface, as well as of the internal dimensions of a drain, necessary to dry a certain space of ground, must vary according to the climate of the locality for which the drain is intended, and not according to the area to be drained. To render this more evident, we have extracted from the Meteorological Journals, published monthly in the "Annals of Natural History," the following Table, showing the monthly quantities of rain which fell in 1843 at Chiswick and Orkney respectively. The Table is as follows:—

Months.	Rain at Chiswick.	Rain at Orkney.
	Inches.	Inches.
January	4.47	3.89
February	0.76	4.44
March	1.88	6.25
April	2.35	1.32
May	0.47	2.46
June	1.62	4.05
July	5.26	2.21
August	1.62	1.04
September	1.67	2.92
October	3.32	1.84
November	0.90	2.
December	4.19	6.35
Total in the year	28.65	38.89

From this it will be seen that the total quantity of rain last year was one fourth more at Orkney than at Chiswick; and by Dr. Dalton's Tables, compiled from the Transactions of the Royal Society and other sources, we find that the annual mean quantities of rain in different parts of the country vary from 27 inches, amongst the mountains of Cumberland, to 20 inches, in Essex; the mean of all England and Wales being 31 inches. No uniform rule as to the area of porosity or the internal dimensions of drains can therefore be given, without reference to the locality and climate for which the drains are to be calculated.

The next objectionable proposition of Mr. Mechi is the assumption that the superfluous surface-water should run off through the drains within the same space of time in which it fell from the clouds. Now if we attend to the actual state of things, as it occurs in nature, we shall find that though water falls during rain, in equal quantities over the whole surface of a field, yet, as the drains by which it is to be carried off are placed at certain intervals in the field, the water must run into them unequally, some part of it having to filter through a greater distance in order to reach the drains than the rest. Whatever, therefore, be the area of porosity of the drains, the water cannot escape as rapidly as it fell. And further, it appears pretty certain that it is not even desirable that water should escape so rapidly, even if means could be found to enable it to do so. The gentle percolation of rain-water through the soil, accompanied by air and other gases, is probably highly beneficial to vegetation. It therefore appears that the conditions of perfect drainage are sufficiently fulfilled, if the area of the drains be such that all superfluous surface-water is in a constant state of motion towards the drains till it is ultimately carried off by them.

If we now proceed to offer a very rough approximation to the size of drains necessary to secure the condition of perfect drainage above described, we shall probably find that the dimensions of Mr. Mechi's drains, instead of being too small, are unnecessarily large, and that great waste of capital has been hitherto incurred in draining land, from the drains having been made much more capacious than necessary. We do not allude at present to the large deductions for evaporation and for the consumption of the plants growing on the surface of the land, to be made from the amount of rain which falls in any locality before it reaches the drains.

But assuming for a moment all the water which falls upon a given surface of ground in any locality to be carried off by drains, let us inquire what the size of the drains must be in order readily and surely to effect this at all seasons. Referring to the same meteorological journals as before, the following is a Table of the greatest amount of rain which fell in any day, and in any three days in each month of last year at Chiswick and Orkney respectively:—

Months.	Chiswick. Inches and decimals of rain on each of 3 most rainy days.			Total of 3 most rainy days.	Orkney. Inches and decimals of rain on each of 3 most rainy days.			Total of 3 most rainy days.
Jan.	0.87	0.67	0.37	1.91	0.29	0.10	0.81	1.20
Feb.	0.32	0.20	0.09	0.61	0.59	0.57	0.36	1.52
March	0.29	0.12	1.16	0.57	0.92	0.71	0.51	2.14
April	0.26	0.28	0.26	0.80	0.29	0.26	0.35	0.90
May	0.21	0.08	0.06	0.35	0.49	0.27	0.40	1.26
June	0.22	0.23	0.35	0.80	0.41	0.41	0.47	1.29
July	1.26	0.58	0.57	2.36	1.12	0.55	0.27	1.94
August	0.23	0.64	0.20	0.79	0.57	0.13	0.12	0.82
Sept.	0.24	0.50	0.16	0.90	0.95	0.65	0.45	1.95
October	1.02	0.61	0.95	2.59	0.36	0.35	0.25	0.96
Nov.	0.52	0.20	0.24	0.96	0.29	0.36	0.24	0.89
Dec.	0.88	0.34	0.52	1.47	0.60	0.47	0.53	1.60

N.B. In the above Table the three days' rain were never continuous, but the three most rainy days are picked out of each month promiscuously.

From the above Table it appears that though the whole quantity of rain which fell in 1843 was much greater at Orkney than at Chiswick, yet that on particular days more fell at Chiswick than at Orkney. Probably the soil would be less saturated with rain at Chiswick than at Orkney, so that the extra quantity which occasionally fell would be more rapidly evaporated, and therefore the extent of drains requisite to free a given space from water would still be greater at Orkney. We do not, however, at present take into account the amount of evaporation. It appears that on only two occasions in the last year did the rain which fell at Chiswick in one day ever reach one inch, and only once in that year at Orkney; if, therefore, drains are calculated to allow *one inch* of rain to run off in *three days*, they would have been sufficient last year for either Chiswick or Orkney, without reckoning the amount carried off as vapour by evaporation, or for the supply of vegetation. What area of drains, then, is necessary in order that the land shall be freed from one inch of surface-water in three days? Supposing the drains made at intervals of 18 feet, each would receive the water from a distance of 9 feet on each side of it, each foot of the length of the drain would correspond to 18 square feet of ground, and these covered by one inch in depth of water, would carry exactly one cubic foot and a half for each longitudinal foot of drain. Hence at the end of a drain 300 feet long, (which is the length recommended by Mr. Mechi), there would be 450 cubic feet of water to pass off in three days. This comes to 1 cubic foot of water in 10 minutes, or 172 cubic inches of water to be discharged every minute. But as Mr. Mechi says that a drain should not run above half full, let us estimate the quantity of water to be discharged at double its actual amount, or at 344 cubic inches per minute. Assuming a very small velocity in the water running out of the drain, viz., that of only 30 feet or 360 inches per minute, the area of the end of the drain would not require to be quite one square inch. This sectional area corresponds to that of a circular pipe not quite one inch and a quarter in its internal diameter, which would be all that would be necessary to hold double the quantity of water which, according to the above hypothesis, is ever likely to run through it in the climate of Chiswick. It is evident that the upper parts of the drains might safely be composed of tiles of even less than an inch diameter, so far as their capacity for holding the water likely to run into them is concerned. Thus, the quantity of water which would run through the drains made by Mr. Mechi on Tiptree Farm, if only half full, would be above ten times the quantity likely ever to find its way into them at one time.

But another most important element must be taken into account in determining the real size of drains requisite in any given locality, viz., the large portion of the water falling upon the ground which is converted into vapour, or taken up by plants before it can reach the drains. In the varied circumstances of different fields at different seasons and under different management, perhaps nothing but actual experience can inform us what allowance it is safe to make for this mode of carrying off water in estimating the amount which must be carried by drains from a given surface.

It would, therefore, be very important to have registers carefully kept of the actual discharge of surface-water, together with the velocity of the current, from the main drains of a certain number of acres of land, compared with the fall of rain at the same place and during the same period, measured by the rain-gauge. The depth of the drains below the surface, their length, and number should also be stated. If these particulars were carefully noted, we have little doubt that it would be found that draining has hitherto been made a far more expensive operation than it need be. These remarks, we hope, may turn the attention of our agricultural readers to the formation of a true theory of drains on the most economical principles consistent with perfect efficiency.—*T. T.*

ON THE BEST SPRING CROPS FOR FOOD.

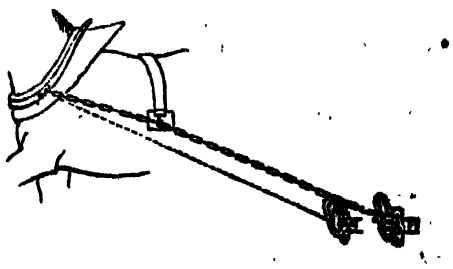
[BY THE REV. R. MORRIS.]

Trifolium incarnatum.—All allusion to the Annual Crimson Clover must not be omitted; of late years it has been sown as a new plant, and was at first highly extolled, its growth being peculiarly rapid in April and May. It does not appear, however, to keep its ground in public estimation. It is thus described by Loudon:—An annual and native of Italy has been recommended by an Italian professor to Sir J. Sinclair, but it is not likely that such a plant, which, even as an annual in our garden borders, has not a fourth of the vigour of the common Clover, should ever be worth culture in this country. This may be rating it much lower than it deserves; yet it is undoubtedly the fact, so far as its cultivation in this neighbourhood is concerned. It has been tried by myself and others on the clay, where it has not succeeded, from the great uncertainty of its growth, at all, and from the meagre quantity it has yielded. Still, as it can be sown on a Wheat stubble without the labour of ploughing, and as it will come in in the month of April, for ewes and lambs, if it should not fail, it may perhaps be prudent to plant some of it this season, on a warm dry soil.

Rye-grass is usually sown with Clover; it is a hardy Grass adapted to most descriptions of soils, and though perhaps of much less value than Clover, as a spring crop, it is earlier, producing (at least at first), food of a better quality than the Clover itself does alone. The expense of seed and cultivation being small, and the uncertainty at all times of getting the Clover to stand, causes its almost universal use, as a Grass seed, to mix with it. "It has been cultivated for a great many years, certainly previous to the year 1677, and it is only lately that any other species has been tried as a substitute for it, in forming artificial pastures. One peck of Rye-grass, with 14 pounds of Clover per acre, is generally considered sufficient for sowing artificial pastures." The sorts most generally preferred are Russell's and Pacey's; but the Italian species is considered far superior to any other. "It is described as peculiarly excellent. It has been sown with Barley without injuring the crop, and by sowing a little thinner, it is found not to choke the Clover in the first crop, whilst its quick growth enables it to keep a-head of it in the second, producing hay little inferior to the first." At a Meeting of the Edinburgh Agricultural Society, it was stated by Professor Traill, that it was proved in the experimental garden of

* We by no means wish to be understood as approving in all their details the measures which Mr. Mechi has lately taken at Tiptree; but that does not hinder us from honouring his patriotism, and heartily wishing him success in what, at considerable risk of private loss, it has induced him to undertake.

the Duke of Buccleuch, to arrive at maturity much earlier than any other perennial Rye-grass, and to produce nearly double the quantity. The experiments made upon it indeed show that it is decidedly relished by cattle in pasture, and in hay; having been given to horses, along with that of the common Rye-grass, in separate bundles, it was uniformly preferred. When allowed to ripen, it gives double the produce of common Rye-grass, and "the nutritive substance extracted from the herbage, affords more saccharine matter than that of the celebrated sort known as Pacey's." An intelligent and practical agriculturist in this neighbourhood has kindly favoured me with the result of three years' experience in this kind of Rye-grass. "In the first year," he says, "I sowed ½ bushel per acre with 10 lbs. of Cow-grass, and had an excellent plant of both. In the following spring the Rye-grass was earlier and more luxuriant than the Clover. I early stocked the field with sheep and lambs, both of which did extremely well. So fond were they of the Rye-grass, that they disregarded the Clover, and trod it under foot as unpalatable; nor would they touch it so long as the least portion of Rye-grass could be obtained. I never saw a field of the same size carry more stock during the summer, (which was genial); nor could the sheep be desired to thrive faster or to be more healthy. In consequence of the Clover being refused, I sowed 1 bushel of Italian Rye-grass and 4 lbs. of Dutch Clover the second year, which answered equally with the first year's growth, and was altogether satisfactory. I obtained in this year about 40 bushels of seed after having grazed the first crop, and shut up the field the last week in May. It is very difficult to secure the seed without loss, especially if it be allowed to stand to get ripe. I intended, and fully thought I should have been early enough; but I was obliged to thresh it in the field upon large sheets, or a great portion of the seed would have been lost. I mixed the threshed hay of the Rye-grass with Barley-straw and made it into a rick. The cart-horses ate it with great avidity, preferring it to very good hay. In the spring of 1843 I sowed 2 bushels of Italian Rye-grass and 4 lbs. of Dutch Clover per acre, and did not find too much plant. It has carried a fair number of stock, but allowance must be made for the extreme dryness of the season. I have lately carried a field of Wheat grown on very good land, which had been fed and stocked heavily two years with sheep. The straw is short but the ears good. I am inclined to think that the Italian Rye-grass had considerably exhausted the land, or the Wheat would have been heavier. If the next crop of Wheat grown after Rye-grass be light, I shall then be convinced of it. I sowed 2 bushels last spring with Clover-seed amongst Barley—the former is a good plant, the latter a failure; I have, therefore, little doubt about obtaining a plant in any season." The excellent properties of this kind of Rye-grass I have had confirmed by the testimony of two other very experienced agriculturists of this district, who have quite abandoned the common sort for it. In March the blades were 14 to 16 inches long, with the seed formed. It carried 20 sheep with their lambs to the acre, five weeks; thus affording a healthy and very nutritious food; sheep and lambs thriving well upon it at the most trying season of the year. In respect to the whole of this class of produce, it has been very sagaciously suggested by a near neighbour of mine, that the distinguishing advantage appears to be early maturity; but on the other hand may not the question be asked, Are plants so nearly allied in nature to Wheat equally valuable for ameliorating crops, with those in which a more marked difference appears? When we consider that in no one quality is Red Clover much inferior to any, and in many far more valuable than most others, we need not wonder that it is and has been for a long time grown to a far greater extent than any. It is moderately early in its growth, its produce abundant and nutritious, adapted for soiling, making into hay, or for pasture; and is considered by writers on Agricultural Chemistry, as well as by practical farmers, as the best preparatory crop for Wheat. The species called Cow-grass is rather later in flowering, and appears in most respects (if there be any difference), rather inferior; it is perennial, growing as a natural pasture Grass on some soils, and on that account is sometimes preferred, where land is intended to be left several years for pasture; though in most cases, like the Red Clover, it is lost after the second year. Cattle grazed upon it are not so liable to be blown or hoven as on the other, which may indicate that it is not so succulent, but it renders it safer as a cow-pasture. All things considered, the Clovers are perhaps the most valuable of the green crops that are grown; but alone they are not sufficient to supply the want that is felt in the present system of farming, of green crops frequently alternating with Corn; for if too frequently repeated, their growth is uncertain; the land—to use the common expression—gets sick of it. The produce of Cow-grass is very great, yielding when in flower, per acre, on a rich black loam, 9 or 10 tons, and of nutritive matter, 6 or 7 cwt.; but the long-rooted Clover is greater still, since a rich clayey loam yielded 30 tons, and of nutritive matter upwards of 20 cwt. These Clover-grasses contain the phosphate and sulphate of lime; hence peat, wood-ashes, and gypsum, are said to be excellent dressings for this crop, and have in many cases succeeded in renovating Clover-sick lands. It seems almost superfluous to observe, that the mode of sowing is almost always broadcast, amongst Wheat or Barley, being either harrowed or hoed in. The quantity of seed per acre should be about 14 lbs.; and if sown with Rye-grass, it is perhaps preferable to sow them separately, as the difference in weight of the two seeds is very considerable. On the clays the plant is more certain with a Wheat than a Barley crop.



Winter Tares or Vetches form an invaluable production of spring and summer food for cattle. They are very extensively used as a fallow crop; for if got off early, and the months of July and August are favourable for the operation, a good fallow may be made, without the entire loss of a crop. Yet, as this depends so much on the state of the weather, it cannot be concluded that a complete fallow is unnecessary. For quantity of produce at one cutting, Vetches stand unrivalled, and their quality is not less valuable. If cut young, a good second crop may be grown in some instances; but, as a general practice, it does not appear desirable. An early variety has been introduced within the last few years; and although decidely earlier (say two or three weeks), in flowering it is scarcely equal in produce to the other. The winter Vetch, so called in contradistinction to the spring Vetch, though they are scarcely different in appearance from each other, is usually cultivated by one furrow, on the stubble. It is questionable whether two ploughings would not be better, provided the time after harvest permitted. It is usually sown without dung, and on rich kindly clays the crop will be good without its assistance; but land in poor condition, and naturally light soils, should be manured. When there is time to give only one furrow in autumn, the dung should be applied on the stubble. The winter Vetch may be sown alone, where it stands the winter well, at the rate of 2 to 2½ bushels per acre, but a little Rye amongst it—about 1½ bushel—protects it from frost, serves as a support, and augments the forage crop in spring. It may be sown in August if the Wheat crop will allow of it; but there is the risk of its being so forward as to be cut down by frost in January. It would be well, perhaps, to sow some in August, and again in September, and a third sowing in October, both for security and a succession of spring food. It is preferable to drill rather than broadcast, as there is an opportunity of hoeing the land between them. As the great merit of this crop is its quantity, it will produce disappointment if sown on land in bad condition without manure, as I found to my cost the year before last. It is stated that in 3000 grains of the green herbage of the common Vetch, there consists of—

	Grains.
Woody or indigestible substance . .	557
Water	2250
Nutritive matter	193

No crop better repays the addition of any organic fertilisers. The soil preferred by the Tare is clay, and therefore it is of so much value where Turnips cannot be profitably cultivated. The produce of Tares cut green is, according to Middleton, 10 or 12 tons per acre, which is a large crop; and when made into hay, at about three tons per acre. If sown in August and not cut off by frost, they will be fit for use early in May. If cut green, Professor Thaër observes, they draw no nourishment from the soil whatever; while made into hay, they afford a fodder preferred by cattle to Pea-straw, and more nutritive than hay or any other herbage. Horses, cows, sheep, hogs, all feed and flourish upon them; hogs are soiled upon them in Sussex, without any other food. They are liable to few or no diseases. Sometimes, but not often, they are injured by mildew. There is a sort called or known by the name of the "racers," which are highly spoken of. It is stated of them, that being planted on the 26th of August, in the proportion of 1 bushel of Rye to 2½ bushels of Vetches per acre, the Rye sown on the furrow and the Vetches drilled across, which seeds the land all over beautifully, on a quantity of land of moderate description, in a very exposed country, they had attained their full maturity on the 5th of May, but were fit for feed a fortnight before, surpassing all others in that neighbourhood. This variety is undoubtedly more hardy, and at least 10 or 12 days earlier in the growth and fitness for feed—the early sowing thereby covering the whole surface of the land before winter, the mixture of Rye keeping off the frost and supporting the Vetch, by which means a circulation of air at the bottom no doubt promoted their early growth. From these remarks it will be worthy of consideration whether it would not be advisable, in the present peculiar season, when we have, contrary to all past experience, lost both our hay and Turnip crop, and especially that invaluable friend the Swede, to sow a small portion of Rye as quickly as possible; also some winter Vetches—the "racers" if they can be got—with Rye mixed; and it might be well to try on suitable soils the Trefolium incarnatum; these might be followed next month by further sowings of winter Vetches, so that there might be obtained food for cattle from the middle of March through the spring.

ON THE YOKING OF CATTLE TO PLOUGHS.

In a Leading Article of No. 36 of the *Gazette*, there are some remarks by a correspondent on the mode of harnessing cattle to implements, and in particular to the plough, in which it is stated that the attachment of the draught-chain to the back-band affords a mean of altering the line of draught. From this assertion I beg leave humbly to dissent: it appears to me that such attachment should always be as loose and easy as possible, and merely for the purpose of keeping the chains close to the sides of the working animal. I think that far from having the effect ascribed to it, of "bringing the muscles of the back into play, and increasing the capability of the animal," the tightening and compressing of those muscles by the forcible drawing down of the back-band must have the directly contrary one of inconveniencing and hurting him, and therefore of impeding his motion. Ill-fitting and especially tightness of any part of the harness must, I think, always be productive of uneasiness to a greater or less degree, and consequently of loss of power or force to a proportionate extent. Besides, the bridle, or extremity of the plough, to which the draught-chain is attached, always affords the means of altering the draught as the ploughman wishes, both as to depth or shallowness, and width or narrowness of the furrow-slice. It appears to me, therefore, that the draught-chain should form one straight line from the collar to the plough-beam, and that any angle at the back-band must tend to a loss of power.—*A. J., Roxburyhshire.*

[We still think that the use of the back-band in the manner recommended by our correspondent, is a relief to the draught animal. It is true that an incidental advantage of it consists in the means it affords of regulating the depth at which the plough shall work; but this is not the use chiefly insisted on; if it were, "A. J.'s" indication of the arrangement at the bridle of the plough, as being the legitimate means for this purpose, would be conclusive. The use of the back-band in the manner in which it is represented at work in the above figure, which we reprint, obviously tends to divide the strain of the implement between the shoulder and the back. The strain upon the shoulder is not so great when the back-band is thus at work as if the draught-chain were perfectly straight. To be sure, the strain thus imposed upon the back is greater than the differential advantage thus obtained by the shoulder; but not only is the horse, we think, better able to sustain the greater strain thus put on a fresh set of muscles than he would be to sustain the smaller additional strain which would have been sustained by an already overloaded set, but the pressure thus placed on the back makes him, we think, better able to overcome whatever strain may be placed on his shoulder. Does it not give him a firmer footing? One of the chief advantages which the use of the cart possesses over that of the waggon, consists not only in the horse, as it carries part of the load, not having the whole of it to draw, but also in the firmer footing afforded by the weight on the cart-saddle, which would enable him more easily to draw the whole weight, would make him, *à fortiori*, better able to draw that which is thus diminished. As a proof of this we may relate an anecdote, the particulars of which were detailed to us by an eye-witness. A horse in a cart was drawing stones from out of a quarry, the approach to which was a descent. When the cart was loaded, the labour connected with it was found to be beyond his power. In order to remedy the evil, the stones were placed more forward in the cart, thus not only placing more of the load on the back of the horse, and leaving less for him to draw, but firming his footing, and therefore enabling him to put forth greater exertion. But "A. J." may say that the advantage thus afforded the animal lay altogether in the first of these particulars, not in the second. He cannot say so of the next measure that was taken, for it was found that the horse was still unable to extricate the load. The man was ordered to mount him; the advantage which the animal obtained by the additional weight, and consequent firmer footing thus given to him, so much exceeded the disadvantage which we must presume he experienced from having an additional load to carry, that the next effort he put forth was successful. The advantage of any arrangement by back-band or otherwise, by which the strain, whether it be in the draught of cart or plough, may be partly laid upon the back of the draught animal, and only partly on its shoulders, is thus made apparent.]

ON MINERAL AND INORGANIC MANURES.

No. XXVII.

By Professor Charles Sprengel.

(*Continued from page* 644.)

3. *Dutch peat-ashes*, worst quality (yellowish gray) 100,000 parts consist of—

70,000	parts	of silica.
4,134	,,	alumina.
6,131	,,	lime.
3,930	,,	magnesia.
4,096	,,	oxide of iron, and a little protoxide of iron.
0,200	,,	protoxide of manganese.
0,040	,,	potash.
0,420	,,	soda.
3,395	,,	sulphuric acid, combined with lime and potash.
1,246	,,	phosphoric acid, combined with lime and iron.
0,464	,,	chlorine, combined with sodium into common salt.
5,544	,,	carbonic acid, combined with lime and magnesia.
100,000	parts.	

4. *Peat-ashes from Lüneburg*, found to be a good manure (reddish-yellow). 100,000 parts consist of—

51,700	parts of	silica.
5,070	„	alumina.
31,889	„	lime partly combined with silica.
0,960	„	magnesia.
17,728	„	oxide of iron, and a little protoxide of iron.
0,520	„	protoxide of manganese.
0,120	„	potash.
0,072	„	soda.
6,166	„	sulphuric acid, combined with lime into gypsum.
1,183	„	phosphoric acid, combined with lime and iron.
0,084	„	chlorine.
4,486	„	carbonic acid, combined with lime.
100,000	parts.	

Of the peat-ashes No. 1, 3000 lbs. are often used on one Magdeburg acre of land; as thereby about 180 lbs. lime, 300 lbs. gypsum, 48 lbs. common salt, 150 lbs. magnesia, and 120 lbs. phosphate of lime, are conveyed to the soil, it may easily be understood why the industrious Belgians value them so much. Gypsum, common salt, and phosphate of lime are the substances by which they act most powerfully. 3000 lbs. of peat-ashes per acre may appear much, but if only 1000 lbs. should be applied, the gypsum only could be expected to act, as the other substances would not be present in sufficient quantity to benefit the soil. If the above quantity be new it will act for 5 or 6 years. Of the Lüneburg peat-ashes still greater quantities are used, viz. 3 or 4 tons per acre, and by such quantities the texture of a clayey soil will be improved.

We may conclude, from the component parts as well of this as all other peat-ashes, that they can decompose but little the humic parts of the soil; they serve the plants mostly as food; and as, in the main, they do not possess much of the easily soluble salts, even a greater proportion than the above stated might be applied per acre without any chance of injuring the crops. It is the small quantity which has been hitherto used of peat-ashes which has led to the opinion that they are worthless as a manure, whilst occasionally a great quantity has not produced any effect, because they contained a salt not easily soluble in water, for instance sulphate of iron; or because they contained much of phosphate of iron, which, if not soluble in water, is so in liquid humic acid, by which the plants were supplied with more iron than they could bear. Peat-ashes, however, which contain sulphate or sulphuret of iron, are, as we shall hereafter see, amongst the most valuable manures, if used in small quantities, and they entirely supply the place of gypsum.

ON THE REGISTRATION OF FACTS TENDING TO ILLUSTRATE QUESTIONS OF SCIENTIFIC INTEREST.

RUST IN WHEAT.

It was good advice which I once heard given by a dealer in objects of natural history to a friend who had offered to procure specimens for him in some foreign country he was about to visit—"If you really wish to serve me," said he, "do not send me pretty specimens, nor yet anything that you may fancy particularly curious. I am already overstocked with such objects. Just keep a jar at hand, filled with spirits of wine, or gin, and whenever you see some very common-looking reptile or insect, pop it into the jar. The chances are, that everything you may consider least worth preserving will be of most service to me." The fact is, that persons who are not naturalists are no judges of what objects are most likely to be of interest in a strictly scientific point of view. Botanists would rather receive one of our most common weeds from a newly-discovered or newly-explored country than a new species of an already known genus. There are higher departments of botany than mere collectors of specimens are aware of. To ascertain the geographical distribution of a well-known species is a point of vastly superior interest to the mere acquisition of a rare specimen. My friend Darwin well understood this (but then he is an accomplished naturalist), when he so often stepped aside from his geological and zoological pursuits, to preserve specimens of plants for me; though botany formed no portion of his immediate studies. I suppose there are few persons possessing a healthy taste for the details of real adventure, who have not by this time read his most interesting "Journal of the Voyage of the Beagle;" and from what they must there have seen of his appetite for observation, they will not be surprised to hear that I have just received from him two blighted ears of Wheat, which few persons would have thought it worth while to carry with them round the world, but which he brought home upon the chance of their affording some information on the cause of those extraordinary and devastating blights to which the crops are occasionally subject in South America. As the memorandum he has made upon the subject will possess an interest in the eyes of agriculturists, I shall here present it to your readers; and then mention the cause to which these blights must be ascribed:—

MR. DARWIN'S MEMORANDUM.

"*Northern Bank of the Plata, Nov.* 20-30, 1833.

"No. 1593.—Bearded Wheat materially injured by a blight, called the 'Polvillo.' When a field is attacked, it seems, even at a distance, burnt up, and of a red appearance. On walking amongst the Corn, the shoes and trowsers become covered with a fine rust-coloured powder: hence the name. The powder is lodged in minute oblong patches, beneath the epidermis, which may at first be seen partially raised, and forming a scale. It attacks all parts indiscriminately. If the leaves are a little infected, the grains of Corn are light and dry; but if the ear and stalk are attacked, the crop is entirely spoilt. The blight is not observed before the grain is pretty full; and its attacks are very rapid—three or four days being sufficient to spoil a whole field. It is endemic in the whole district, though not equally destructive throughout. From this cause, last year, when the weather was wet, no grain was gathered. Hence an immense importation of flour took place from North America. This year, the weather being fine and dry, the blight will destroy or injure the greater part of all the crops. Fields thrown up in Buts, clear of weeds, on high ground, are equally attacked with those of less favoured aspect. It is here attributed to the sun's action after heavy dews. Crops grown from grain of the country, from the Cape of Good Hope, and from Rio Negro in Patagonia, were all more or less affected. It is remarkable that the Wheat at Rio Negro itself (which is grown on low diluvial lands) produced, even last year, its immense crop uninjured. This blight is a prodigious evil to the country, and most mortifying to the agriculturist, who does not know that all his labour will be lost, till within a week or fortnight of the time when he was expecting to reap the fruits of it."

This account of Mr. Darwin's would alone have inclined me to suppose that he was describing an example of a very virulent attack of rust or redgum, a form of fungus which I have noticed in the Journal of the Royal Agricultural Society, vol. ii. p. 9, and again at p. 220, where I have endeavoured to prove its specific identity with mildew. The two forms of rust with which we are acquainted in England have been termed Uredo rubigo and Uredo linearis; and it should seem that the form which ravages the banks of the Plata is the latter, for I sent one of the two specimens with which Mr. Darwin supplied me to the Rev. M. Berkely, who is far better authority on such a point than myself, or than any one else in this country. His remarks are as follows:—"Your rust appears to me the same with what I have received from Ohio, and agrees with our European species, which is referred to U. linearis, distinguished from U. rubigo vera by its longer spores, and by the more inflated cuticle of the sori. I believe U. rubigo vera to be the young of the common mildew. I have never myself gathered U. linearis. The La Plata specimen exhibits plainly the mycoloid base. I have also U. rubigo vera from Ohio with the European characters."—*J. S. Henslow, Hitcham, Sept. 9.*

ON SEA-WARE.

Some of your correspondents have noticed the properties of the Alga marina, and the modes of using it, but not so fully perhaps as might have been expected. The names of Varech, Wrack, or Wreck, by which it is designated by the farmers on the coasts of Brittany and Ireland, where the Celtic is the vernacular language, explain to the etymologist their true signification—substances thrown up or torn away, as the sea-weed is, by the force of boisterous waves. Strange to say, the authors of the "Cours Complet d'Agriculture" have asserted, without even a modest doubt of the correctness of their judgment, that all marine plants, so called, are animal productions, though resembling the latter in form and organisation: they considered them to be either the remains of animal matter or the receptacles of animals, confounding all the tribes of Algæ marinæ with coral fabrications, &c.

The primitive mode of using sea-ware was, probably, that of spreading it on pasture land; the more artificial system of applying it to the formation of composts, and the blending of it with the soil by the plough or spade, were subsequent steps in the progress of husbandry; yet, though various methods of combining this substance with the earth have been adopted, there is no uniformity of practice observed. The spreading of sea-weed very thinly and as fresh as possible produces a rapid alteration on coarse and unsavoury pasture; the quality of the herbage unequivocally shows the beneficial effects of the saline substances which the weed contains, and the cattle which feed upon the new Grasses improve in health and condition.

The best season for putting out sea-weed in this way is in the early part of the spring, at which time too it yields the most abundant supplies; but unless the fields be adjacent to the coast, and the quantity of weed excessive, I do not consider this so economical a mode as that of mixing it with other substances in compost, or that of spreading it on stubbles, if in the winter season, and ploughing it into the ground, by which means it becomes an active agent in decomposing the short straw, which otherwise would be suffered in many instances to wither away on the surface of the land, instead of being rotted and incorporated with it.

It is a common practice in some parts of Ireland for the peasantry whose fields may be a few miles from the strand, to collect and dry the weed in the latter part of spring, if it should at that period be wafted to the coast, and to convey it when dry from the influences of the sun and wind, in large bulk to their Potato-drills, over which they shake it thinly, but not actually in contact with the germinating sets, which perhaps have been in the ground a fortnight previously. This mode, however, indicates the inability of the person who so uses the weed, to manure his crop at the usual time, and with a better material. Four moderately-sized (one horse) cart-loads saved in the above way is sufficient for a rood of Potatoes, the ultimate success of which is most uncertain, depending on the timely application of the weed (which in a calm season may not be collected), and the subsequent humidity of the atmosphere. As regards the succeeding crop of Corn, this mode of applying the weed is the most defective; but the immediate effect upon the vegetation of the plant from the absorption of the saline matter is very apparent, though I have never seen large tubers raised in this way (nor very farinaceous ones with any modification of the manure in question), comparatively with the other methods. In dry weather the weed lying on the surface shrivels up; but when affected by moisture it expands again. The salt, which does not evaporate like gaseous matter, acts in a humid atmosphere continually as a stimulant; yet common salt, if scattered over the ground, would not serve in the same manner. There must, therefore, be certain combinations formed that favour vegetation, by means of the excessive susceptibility of absorbing moisture from the atmosphere which the Algæ marinæ possess.

On the coasts of Brittany and parts of Normandy, sea-weed is sometimes reduced to ashes in order to obtain the alkalies they yield by this process for manure (I am not alluding to the common operation of kelp-making), which is spread on the surface. This, I think, is a wasteful way of using it. The most generally convenient and profitable manner of converting sea-weed into manure is to remove it from the beach as soon as circumstances admit, and to lay it on a substratum of sand, loose mould, or scourings of ditches, to absorb the oily juices and salts which the weed contains, until he can find leisure for taking it away. The force and rapidity with which the fluid penetrates through the subjacent layer, and rots whatever vegetable substances it may contain, is astonishing. In the course of putrefaction the weed generates maggots and flies in immense quantities—a living testimony to the richness of the matter which produces them. For stiff soil, which this weed of itself has a tendency to render still more cohesive, a mixture of sea-sand is preferable to that of clay, as the latter would answer better for a light sandy soil; but any calcareous sand and a rich loam can never be otherwise than valuable recipients of the sea-weed, which should be fully blended with the substratum, whatever that be, until the whole becomes a black mass of well-pulverised compost, which any one possessing the sense of smelling will perceive to contain a great portion of carbonic gas—the principal food of plants. A compost of this nature is a chief resource of the farmers in the baronies of Forth and Bargie on the Wexford coast; without it many of them would be poor indeed; by means of it they are enabled to raise some of the heaviest crops of Beans and Potatoes that I have ever seen.

In the Sketches of East Lothian Husbandry it is considered a very useful species of manure for the light dry soils adjacent to the coast, but not advantageous on clays—"immediate, but transient in its effects;" "seldom lasting longer than a single crop." It is certainly much better for light than heavy lands, but I have found it very efficacious on stiff soil also, when applied in the compost form; it is "seldom mixed," in Berwickshire, as the Report continues to state, "with other substances." If it were combined with sand, the mechanical effects of which in loosening cohesive soil are so perceptible, it would be found effective. As to its being transient, "only lasting for one year," so is guano, which, on the high authority of Professor Buckland, is so volatile, that it produces but one crop. But this mode of expression is practically incorrect, for these volatile manures cause the earth to yield two crops, sometimes three; Potatoes or Turnips, succeeded by a Corn-crop, may be followed in many cases by Clover. Though the properties of such manures be too evanescent to afford nourishment to a second or third crop, they are the agents through which the farmer is enabled to pursue the course of preparation of the soil, by which he renders his land productive of the succeeding crops. The great degree of tilth which usually accompanies manured green crops insures, on a soil of good quality, which has not been exhausted by over-production, a crop of Barley succeeded by Clover. Supposing a sufficient quantity of lime applied to the Clover-ley, for Wheat, after it has been fed off by sheep or cattle (not mown), the farmer will find his compost of sea-ware, &c., again successful in the second rotation, immediately after the Wheat; but he will act more judiciously in using farmyard dung, the superior value of which is undoubted, if he can. Judiciously managed, sea-ware, though far less permanently beneficial than other manure, is a valuable auxiliary to any sea-coast farmer, because it affords him the facility of pursuing his regular rotations if the farmyard dung be insufficient; and to the poor peasant it is in countless cases the sole means which he possesses of raising his Potato-crop. But except to husbandmen, whose land is close to the shore, the collection of sea-weed ought not to be systematically an object of anxiety, because the gathering and removal of it, if the distance exceed a very short space, greatly interrupts the regular routine labours of a farm, and occasions much fatigue to the horses employed in drawing it from the shore to the bank, during the busy intervals between the tides which bear it to land; and such labour and fatigue are hardly compensated by the acquisition of it, unless the subsequent cartage be inconsiderable: to the farmers who cultivate the sea-coast of Berwickshire, and who are, in every respect, among the magnates of their valuable order, I can well conceive that an influx of sea-ware is unimportant; to those who can accumulate, *ad libitum*, the best farmyard dung by means of cattle, Turnips, oil-cake, and straw, the extraneous manure which the sea affords, with more or less profusion, is not an object of much value.

But to the petty farmer, who is not "rich in cattle," and more particularly to the Irish peasant, whose pig is his only dependence for the accumulation of half a dozen little cart-loads of manure, sea-weed is indeed a boon, for which he thanks Providence; and if such miserable human beings as those are who occupy the coast of Mayo were once in a condition to maintain a few cows, on the alternate system of green and white crop, and could be induced to raise Turnips, Rape, and Cabbages with composts of sea-ware and sand, they would be enabled to apply the manure generated by the cattle to the raising of Potatoes, which being, in such case, far more abundant in quantity and much better in quality than they are under the present uncertain mode of management would deservedly maintain their character of the "vigour-stirring root" and become a wholesome food, instead of being so decidedly the contrary, as they are when deficient in farina—weak, washy, and innutritious, as Potatoes raised by sea-ware in unpropitious seasons always are. With calcareous sand, or a very moderate allowance of lime, a limited quantity of farmyard manure produces the largest crops of Potatoes, and of the best quality; an excess of rank dung indeed would be as pernicious to the quality of the Potato as a dose of sea-weed; but used in moderation, after an application of lime, no other manure can compete with it for producing the main support of the Irish peasant. The amelioration in the physical condition of the poor occupants of land on the sea-coast, which would be consequent on their adoption of such a system as that to which I have referred—the application of sea-weed to green crops for cattle—would be incalculably great.—*Martin Doyle.*

Home Correspondence.

Two Crops per Annum.—A manufacturer replied to a croaking farmer that, if he could not live with one harvest in the year he must have two, as they were obliged to increase their spindles. Now, in Belgium, through which I passed last week, they appear to approach this desideratum. I saw all the land which had borne a crop of Rye covered with Carrots, and that which had yielded Oats covered with Turnips. The latter I can understand, for I noticed that they did not let the stubble remain even till the Oats were carted, but set the shocks closely in a line and ploughed between them; but how they get the Carrots, I am free to confess, puzzles me. It must answer their purpose for the feed of cattle, to which use they are applied, otherwise the system would not be so general; and why not, therefore, introduce it here? Perhaps, Sir, you will be good enough to investigate this matter, and favour me with the result. I may remark that Rye and Oats seem the only grain-produce of the country; there is very little Wheat or Barley. If Carrots could be produced on our light soils, which grow Wheat, it would greatly help our milch cows in winter, and furnish labour for our too dense population in clearing away the stubble and hoeing the land after harvest, an occupation in which King Leopold's subjects seemed mightily busy last week.—*Cantab.* [We will ascertain the Belgian practice in this particular.]

Wash for Bark of Trees.—Your Correspondent in the *Agricultural Gazette* will find that a wash made of two-thirds cow-dung and one of lime, laid on with a brush, is an effectual remedy against cattle injuring the bark of trees; add a little tar if to protect from rabbits and hares. —*W. Shirley.*

Ireland.—During a journey in the south of this country I stopped at Castle Martyr, in the county of Cork, and found a fine residence of Earl Shannon, and some good farming on a light loamy soil. For some years past that nobleman has imported Ayrshire cattle from Scotland, and has bred them at Castle Martyr, where the land steward pointed out to me the very singular deterioration in the breed, very evident in the general appearance of the animal, and most particularly in the increased size of the horn at the base—a sure mark of bad breeding. It was quite easy to distinguish among the herd the animals bred in Ireland from those imported, the skin and hair being much coarser, the head larger, and the whole frame much deteriorated. I have since learned from a friend in Kent that he has experienced the same result, but not so large in degree. My own experience in Leicestershire did not show any deterioration in a herd of 20 cows, which produced very fine calves from a native imported bull, and which bred again from a male also imported; and the progeny seemed rather to improve in quality. Probably some of your readers may have experienced the above results, which seem altogether inverted.—*D.*

Rooks.—They may now be seen in vast numbers visiting Turnip-fields, for the purpose of feeding upon a species of grub, now very prevalent in many places, much to the injury of the crops; instead of destroying them farmers ought to look upon them as their best friends. The grub in question is a larva of a species of moth (Noctua), prevailing only to any amount in droughty summers, which appear to be congenial to the habits of both larvæ and perfect insect. No serious mischief, I believe, has been done by it to vegetation since the years 1826 and 1827. In 1818, which was a very droughty season, I remember its depredations were so great, that there was scarcely a well-matured Turnip to be seen. Teazles also suffered much the same year, and horticultural productions generally shared a similar fate; it likes all sorts of vegetable food—nothing that falls in its way seems to escape its ravages. The grub during the day-time lodges, in dry weather, just within the earth, near to the plant it feeds upon, and burrows deeper in wet weather. It is produced in the months of July and August, and commences feeding by shearing off the young plants close to the surface; when plants are too large it ascends and feeds upon the young leaves, or what is commonly called the heart of the plant. It continues its depredations until the beginning of October, providing the weather be not too wet and cold; about this time it is full-grown, being about an inch and a half long, and of the thickness of a moderate-sized goose-quill; and after descending a few inches into the earth it becomes dormant, in which state it remains until the middle or latter end of April, when it commences its transformation, and in a few weeks assumes the pupa state, and issues forth about the fore end of June a perfect insect—a middle-sized brown moth, which secretes itself during the day in thickets of vegetables or weeds, and there deposits its eggs. The gardener should now be concerned for his latter crops. Rooks are too shy to visit gardens; but much good may be done upon a small scale, by using a knife, or something similar, to search for the grub where he sees drooping or injured plants. I remember in the year 1818, recommending this plan, as well as the protection of his Rooks, to a gentleman agriculturist, who took my advice and employed a number of women and boys, and thereby secured the better half of a crop of Turnips and Teazles, whilst all others about entirely failed, leaving extensive fields little better than fallow land.—*Joshua Major, Knosthorpe.*

Farm Fences.—At page 266 of last year's *Chronicle*, I made some few observations on the ownership of agricultural fences: the following is a note on the tenant's obligation to repair them. It is so notoriously the duty of the actual occupier of land to repair fences, and so little the duty of the landlord, that without any agreement to that effect, the landlord may maintain an action against his tenant for not so doing, upon the ground of the injury done to his inheritance. It is so decided in Cheetham *v.* Hampson, 4th Term Reports, page 319. —*A Quiet Observer.*

New and Old Land.—In a late article under this head, page 580, there are some remarks which confirm my limited experience as to the want of fertility in an old garden, yet I am somewhat puzzled by the opinion of my favourite, William Cobbett, who opposes what seems to have been in his day, as now, the prevailing theory. The annexed extract I have clipped out of paragraph 115 of his "English Gardener:"—"Mr. Missing, a barrister, living in Titchfield, in Hampshire, has a border under a south wall, on which he, and his father before him, have grown early Peas every year, for more than 50 years; and if at any time they had been finer than they were every one of the four or five years that I saw them, they must have been something very extraordinary, for in those years they were as fine and as full-bearing as any that I ever saw in England."—*Paddy.*

Tiptree-hall Farm.—It may be gratifying to you to know that the first field of Wheat we have threshed at Tiptree-hall Farm has produced somewhat over 5 quarters per acre, of a very fine quality, which sold (as much as was ready) at 46*s.* per quarter in the neighbourhood, being 2*s.* above the ordinary market price of the day. I cannot expect the other 44 acres to produce so much; but I hope they will average 4 quarters per acre. You shall know the result. The crop above mentioned was grown after Potatoes, Swedes, &c., drawn off the land. The cost for manuring the two years' crops was 4*l.* 8*s.* per acre. I need not say this is rather more than a usual Tiptree crop.—P.S. This crop was never estimated by visitors higher than 3½ to 4 quarters: so much for estimates.—*J. J. Mechi.*

Steeping Seeds.—Amongst the various steeps for accelerating vegetation, I have not seen chloride of lime mentioned in your Paper. Some time ago I heard from a friend in Germany of its efficacy; French Beans steeped 4 hours in a solution of a quarter of an ounce of chloride in a gallon of water, were up and in rough leaf before others sown at the same time were above ground, and an equal difference was observable with other vegetables.—*Luser.*

Produce of Wheat.—As accounts of fine roots of Wheat have appeared in the newspapers, I venture to say that Dr. Buckland, who came to East Bourn September 14th to see the 455 allotments of which I receive the rents, there saw a root of Wheat raised from one grain this year, with 125 fine ears 3½ inches long, and apparently averaging 60 grains of Fullard's Prize White Wheat in each ear, and the straw 4½ feet high. Dr. Buckland also saw a hand-basin full of Wheat of the same kind raised by me at East Bourn, from one grain put in the 22d July, 1844, the shoots from which were divided and transplanted twice before Christmas and once afterwards, and yielded—

Roots	178
Ears	3,372
Grains	77,025

Which weighed 7 lbs. 15½ oz.—*Benj. King, East Bourn, Sussex.*——*C.* adds, "On March 1, 1844, I planted four grains of autumn Wheat at eight inches distance and two inches deep; one grain I laid on the surface, and covered it about half an inch deep; the grain produced six stems and ears. Of the four that I planted, one produced 29 stems and ears; the other three produced 22, 21, and 20: thus making in all 92 ears, the average number of grains to each stem was 20; in all 1840 grains. I was induced to try the experiment through the farmers telling me that autumn Wheat would not produce a crop if sown in spring; it has occupied the ground six months and two weeks."

Fence for Trees.—I have seen and heard of many ways of fencing single trees against cattle; the fences generally used are wood and iron, varying in price from 3*s.* to 21*s.* each. I have used for many years, (and have recommended the same to others,) and in no instance have I known it fail,) the following plan, viz., make a circle of stones—the rougher in reason the better—around the tree, at such a distance that no cattle can get to the stem nor branches, without treading upon them: that they will not do, and thus the stones answer for a cheap and durable fence; when no more wanted they are not the least injured, which is not the case with wood and iron.—*J. S.*

Weeds.—Your Correspondents will much serve many in this neighbourhood if they can mention any mode of extirpating what we here call Furze from the pastures (properly, the Rest Harrow—Ononis arvensis), now in full flower, and just seeding. It is the most destructive weed in the meadows, increasing prodigiously, and with its sharp thorns injuring cattle in grazing. We are here accustomed to mow it off, just to prevent the seeding, and, where not thick, digging or spudding it up, and occasionally pulling with pincers; but the long woody roots spread a great distance. If any one once troubled with the Pink Furze or Rest Harrow can say how he has got rid of it, his experience will be much valued.—*H. C.* [We know of no other method of destroying this weed than perseverance in cutting it off and pulling it up. Does any one else?]

Cabbages.—I am a grower of large Cabbages this year, and have, considering the season, been rather fortunate in my crop. As I intend to keep them as long as I can for winter food for my stock, and am also desirous of preparing the land on which they grow as early as possible for the next crop, can you, or will any of your readers, favour me with the best ascertained mode of stacking and preserving them, after they are gathered, through the winter? It is of vast importance to ascertain the best possible manner of preserving such a crop, after gathering it, especially during the ensuing winter and spring, when all cattle food is likely to be so valuable. I shall be very much pleased to receive information from you or any of your readers; and whatever plan I may adopt, I shall derive much pleasure in communicating the result of it, through the medium of your publication. —*Querist.* [We must refer this question to some of our readers. We have never seen Cabbages stored together in any quantity, and have always assumed that the only method is to sow them in successive plots, and consume them as they successively ripen. Sailors keep Cabbages by hanging them individually up by the roots. We doubt the possibility of keeping any quantity together for any length of time.]

FARMERS' CLUBS.

Darlington Farmers' Club.—The September monthly meeting of this Club was held on Monday last at the offices of Mr. Thos. Dixon, Land Agent and Agricultural Engineer, their Honorary Secretary. The subject under discussion was—Wheat-sowing, with the preparation of the Land and Seed, and the proper time for Sowing. In opening the meeting, the chairman observed that the subject they were then met to discuss was one of very great importance to the tillage land farmers of this neighbourhood, and one that he thought deserved more attention than was sometimes bestowed upon it, more particularly with regard to sowing Wheat on Clover leys; and his opinion was, that it was better not to sow when the land was in a very wet state, more particularly in a late season, for in such a case he thought it much better to run the risk of a still later season, and have the land in a tolerably dry and firm state, than to sow it very wet, he having himself experienced the ill effects of wet sowing. He then gave in detail an account of a field of Clover ley, part of which was sown while the land was wet, and the remainder some time later, when the land had got into a drier state; the crop being much superior on the dry sown land than on the wet. The unanimous opinion seemed to be, that it was desirable to avoid sowing when the land is in a very wet state; and, whether sown broadcast or drilled, it is better not to sow the land too soon after being ploughed, as Wheat is found to answer much better when the land has been ploughed a while beforehand; the seed then gets a firmer bed, which is now believed to be very essential to its success. With regard to the preparation of the seed, it was believed that, in all ordinary cases, the method at present followed in this neighbourhood as a preventive for smut answers well; which is, wetting the seed thoroughly with stale urine, and afterwards mixing it with quicklime; or where urine cannot be had in sufficient quantity, salt and water is used in lieu of it; the preference, however, is given to urine, where it can be had. It was also believed that where it is unavoidable to sow smutty Wheat, one of the best remedies known is to wash it in vitriol water, instead of wetting it with stale urine. Drilling and ribbing Wheat was considered by the members preferable to sowing broadcast in all cases where practicable, as by that means the land can be hoed whilst under crop, and kept much cleaner, and thereby not exhausted by growing weeds. It was also considered that a less quantity of seed per acre than what has been generally sown would answer equally well, if not better; and where two bushels per acre has been regularly sown, it was believed that six pecks per acre would be sufficient. And in support of this principle Mr. Joseph Johnson mentioned an accidental circumstance which happened in his own practice, which was as follows:—Some years ago, having as usual prepared the seed-Wheat in the morning for the day's sowing, it happened from some cause or other (he believed from the urine being too strong) that such parts of the seed that were sown in the early part of the day sprouted as usual, and grew well, but such parts as were sown in the latter part of the day came up very much thinner, a considerable portion of it not having

vegetated at all; that part of the field which was sown in the latter part of the day looked for some time much too thin, and likely for a failing crop, yet when harvest came it was quite as good if not superior to the other that was sown in the morning. He also further stated that he was now in the habit of sowing less seed than formerly, and he found it to answer better. He also now, in drilling his Wheat, gave it more room betwixt the rows than formerly, and found it to answer better; he formerly drilled his Wheat at 6 inches, but now, and for the future, he would always give it 9 inches betwixt the rows; it thereby tillered better, and was better to hoe and clean. At the conclusion of the discussion it was unanimously resolved,—1st. That it is desirable, in sowing Wheat, to give it a firm bed, and therefore to have the land ploughed a week or two before sowing; 2d. That in preparing the seed, it is important that it be thoroughly mixed with the urine or brine, so that every grain is wet before adding the lime, and then that the whole of it should be well worked together; 3d. That the best time for sowing Wheat is from the middle of October to the middle of November.

Castle Douglas.—We take from the *Dumfries Courier* the following extracts on subsoil-ploughing, from a lecture by Professor Johnston, lately delivered here:—The under soil very often contains what the upper soil requires. Take the example of lime; it has a tendency to sink into the earth, and is retained by the subsoil out of the reach of the common plough; and if thus a sufficient quantity be found in the subsoil, all that is necessary is to use the subsoil plough. There is, however, no little danger in subsoiling * without a proper analysis having first been made. While one farmer near Edinburgh found so much advantage in subsoiling as to make him declare that he had turned up a second time the whole of the city dung, another farmer trench-ploughed a field, and he declared that by such a process he had lost many tons of Turnips per acre, and the reason of this loss was obvious. When the soil was analysed it was found that he had buried the upper soil, which contained 30 per cent. of vegetable matter, under the subsoil, upon which he grew his Turnips, which subsoil contained only 7 per cent. The utility of trench-ploughing is true as a general principle, but it is not universally beneficial. It might be of advantage, before trench-ploughing, to prepare the lands, so that the roots of plants might be allowed to go down to the subsoil and feed thereon as much as possible. Another question regarding the fertility of the soil may be here asked. Must a soil be of necessity fertile if it contains all the ingredients of a soil possessing fertility? Practical experience answers in the negative; and why? Because there may be something in the soil noxious to the plant; and if so, the plant will not grow; and some substances in too large quantities, as, for instance, common salt, oxide of iron, or manganese will prove destructive. If noxious matter is contained in the upper soil, the plant is always sickly; and if this matter be absent in the upper, but present in the subsoil, then the plant has a reluctance to go down; but if it does enter the subsoil it sucks in the noxious matter along with its ailment, becomes poisoned, and cannot thrive; hence the cause why plants for a season, as in braird, &c., appear healthy and fresh, but when they reach a certain stage, their roots having forced into poisonous subsoil, become blighted and die. The subsoil is not easily doctored by surface medicines. Lime to it is only capable of making a partial cure. Another cause of infertility is the excess of water. A great quantity of clay lands are allowed to lie in perpetual Grass, because they are not drained. Though they contain all the richness of soil necessary for abundant crops, the excess of water prevents the development of their riches. The presence of water renders the soil cold. Evaporation draws the heat from the land just as it draws it from a person's hand if dipt in water and exposed to the action of air; and during a smart breeze of wind the air sweeping over an undrained tract of country is much colder than that in another tract similar in every respect, but in being thoroughly drained. A thermometer buried half an inch under the surface of a drained field, on a hot summer day, will rise to 120, but in an undrained field it will not exceed 90 degrees. Bottom-heat is absolutely necessary for vegetation; hence gardeners prefer it to a hot atmosphere. Another fact is, that the colder the ground the more subject it is to be saturated with the dew by night, and the rain by day. We frequently see mist resting and falling on one part of the land, while, without any perceptible cause, it is absent in another spot—and this alternation over a considerable extent of country; and the reason is just because of the dampness and dryness of the soils. The farmer who refuses to drain is punished by an excess of dew and rain; while the farmer who relieves nature by draining is treated with kindness by natural laws, imparting heat and consequently fertility. Excess of water not only prevents the plants from going down, but it also prevents the air so necessary to vegetation from entering the under soil, and little good can be expected unless the air be freely admitted. Draining may be considered the foundation of all other improvements; for, unless the excess of water be carried off, all other improvements will be ineffectual. You cannot allow the air to enter the soil unless the water be carried off, and by admitting air you can change the nature of many noxious substances contained in the soil. In undrained lands the ridges are so much saturated with water, that when rain falls it cannot be received into the soil, but is forced to flow on the surface, carrying with it any soluble substances within its reach, into the ditches, and from thence into the rivers, where portions of it are thrown out or deposited along the banks of the rivers in holms, giving to those alluvial soils their richness, or, what is still worse, carried into the sea and lost; whereas, in drained lands, the rain enters as it falls, and, in the process of filtration, deposits its own riches, while it loses the power to carry off the soluble portions from the soil; but, besides not carrying off valuable matter, it sucks into the earth the upper air with its rich draught of fertilising matter, and as it carries it away by the drains it destroys the noxious matter in the subsoil down to the level at which it escapes. Draining is assuredly a most economical method of farming;—in some localities the whole expense will be covered by the extra crop of the first year, in others in two years, and certainly it will never exceed five years;—so that for a tenant to drain, even at his own individual expense, the returns would be profitable during a lease. Supposing a farm to be fairly rented, in an undrained state, at 30*s.* per acre, and that it would take the maximum term of five years to cover the outlay, and that the draining had improved the land to the extent of only 5*s.* per acre for the remainder of the lease, here would be a clear profit of 3*l.* 10*s.* for every acre, or 700*l.* for a farm of 200 acres so improved. There are different methods of draining land. It should be done so that it would be permanent—not merely to last a lease of 19 years, but to be efficient for 100 years; and hence landlord and tenant should unite in the matter. If the land is rented at a fair price undrained, and the tenant cannot afford to drain it thoroughly, then should the landlord be at the expense, and the tenant pay a fair per centage for the expenditure. If the farmer is averse to this, and can supply labour, then might the landlord furnish tiles, &c., and the tenant the labour. But in whatever way it may be done, it ought to be done thoroughly, so that it may be both a personal and national benefit. Much money has been wasted in draining, by the drains being too shallow. The best practical agriculturists recommend that tile-drains should not be less than 30, and stone drains not less than 36 inches deep. Some persons object to these depths, stating that they won't draw. This objection, however, is long ago exploded, and the necessity of deep draining made apparent by the depth to which subsoiling ought to be carried. The roots of some plants require a great depth of soil. Wheat, for example, will go down 3 feet; and a great number of practical agriculturists subsoil to a depth of 22 inches.

* Professor Johnston probably referred here to *trench*-ploughing, not to subsoil-ploughing, as indeed the next sentence proves. Subsoil-ploughing could never injure the surface soil, provided the land were drained, because whatever deleterious matters might exist below, none of them are brought to the surface by the operation.

Reviews.

Agriculture; its Practice with Profit, elucidated in a Contrast of Oriental and British Usages; in a Correspondence with the Royal Agricultural Society of England. By Henry Newnham. London: Roake and Varty.

The first letter in the series here published is from Mr. Raymond Barker, who, as Chairman of the Finance Committee of the English Agricultural Society, requests from Mr. Newnham, a member of that Society, the payment of the arrears of his subscription for the years 1841, 42, 43, and 44. Mr. Newnham, it appears, had thought that "the Association was, with respect to annual subscriptions, based on the same principles, and governed by the same laws, which obtain in similar bodies, as for instance the Royal Institution, and in associations such as clubs; and he therefore considered that continued absence from its meetings, and the discontinuance of annual payment of subscription, constituted the established mode of seceding from its association." And in his answer, extending over 21 pages, he states the reasons which four years ago induced him to form the resolution of resigning his membership. The reasons he adduces did not satisfy the Council of the Society that any exception from the operation of its ordinary rules in this matter should be made in his favour; and in the remaining letters of this correspondence, the reader is informed that Mr. Newnham, having "no inclination to have aught to do with the lawyer of the Society," paid up his arrears, and received an official acknowledgment of the same from Mr. Hudson, the secretary.

It is to the second letter, the chief feature in this correspondence, that we would direct the attention of our readers. Excepting one point, on which, however, though he classes it amongst his reasons of withdrawal from the Society, Mr. Newnham does not appear to lay so much stress as it deserves, we think it not difficult to justify the Society from the charges here brought against it; their truth may be admitted without rendering its Council blameable for impolicy, injustice, or want of skill in conducting its affairs.

The first objection raised by Mr. Newnham to the proceedings of the Society, is the effect which he insinuates they have had of diverting the views of farmers from the results of ordinary experience, or from what he calls natural chemistry, to the theories and speculations of scientific men, as the proper foundation of practice. He refers especially to the expectations which have been held out, that the progressive advance of chemistry may aid in developing the resources of British agriculture. His motto is "Practice with Profit," in contradistinction to that of the English Agricultural Society, which is "Practice with Science." It appears to us, that he supposes the motto of the Society to be expressive of the end for which they labour, instead of being expressive, as it is, merely of the means by which they propose to obtain a profitable end. It is too late now to rail at science as visionary and baseless. The evidence in support of the facts, the accumulation and classification of which constitute science, is stronger far than that on which most of the crude notions are built of many of our thoroughly practical men. We have now men who can testify from experience to the profitableness of uniting practice with science; and this testimony is unaffected by the lamentations of others, who may be insolvent as farmers, not from having adopted such a union, but from breaking it, and attempting to carry on their business unassisted by one of its essential elements—experience. Natural chemistry—for so Mr. Newnham dignifies the results of agricultural experience—which points out the advantage of chalking clays and marling sands, and of employing as manures farm-yard dung, peat-ashes, rags, lime, &c., so far from having been neglected, has been much enforced and explained by the application of chemical science to agriculture, under the auspices of the Society.

The second reason which Mr. Newnham gives for having seceded from the English Agricultural Society is "the encouragement which," he states, "they have held out to the substitution of mechanical power for human labour." He alludes to their annual award of premiums to further the improvement of our agricultural mechanics. His objection, if reasonable, must apply not only to Agriculture, but also to all industrial employments; and there were, doubtless, many patriotic and well-meaning men who objected half a century ago to the improvement of the machinery of our cotton and woollen factories—to the very means, in fact, as they have since turned out, by which the numbers of those employed in these factories have been a hundred-fold increased. This result has depended on no accident peculiar to the cases in which it has been realised; it is merely a consequence of the natural connection which exists between an improved and cheapened means of production and an increased consumption of produce; and we believe that in Agriculture, also, any means which cheapen the cost of production are thus productive of national benefit; it may be difficult to follow them through all their influences, but we may depend upon it that they will terminate in causing what is termed higher farming, and in the employment of more labour than ever. Mr. Newnham here digresses into an account of the various practices of Indian Agriculture, a chief feature of which appears to lie in the custom of paying for labour according to the produce of the land—the fraction of the produce which falls to the share of the workman being inversely proportional to the abundance of the harvest.

Mr. Newnham's third reason for withdrawing from the Society, viz.—its disregard of the subject of parochial assessment, however accurate his views on the matter may be, is obviously insufficient, if we consider the nature of the tie which holds the Society together. The exclusion from the subjects of the prize-essays of a matter of such vital importance to Agriculture as the present mode of assessing the poor's rate is a consequence of the law which, we believe, lies at the foundation of the Society's existence—the law which forbids the discussion of matters to be brought before Parliament.

The liability which hangs over every farmer who commences the work of agricultural improvement—his liability to an increased charge as respects all parochial rates—involves the apparent injustice and obvious impolicy of assessing that man most for the support of the poor who employs the greatest number of them, and him least on whose non-employment of them the existence of pauperism may chiefly be chargeable. It would be well, we think, if security by legal enactment from this liability were given to agricultural improvers for terms of years, varying according to the permanency of the several descriptions of improvement which they may have effected.

If we have hitherto been exhibiting reasons for withdrawing from the Society, the entertainment of which may appear reasonable to many minds, and may even to some justify the step which Mr. Newnham has taken, we fear that the sympathy which that gentleman has thus experienced will not continue to follow him while he details his fourth reason for seceding. He withdraws from the English Agricultural Society "because they have altogether overlooked and disregarded the science of Astronomy!" Had the word been Astrology, it would have been more in keeping with the singularity of the idea. A capability of prognosticating the weather, which he thinks a skilful application of Astronomy to Agriculture (!!) would confer, would doubtless, in our variable climate, often prove of great service to farmers; but this is to be obtained, not by carefulness in recording astronomical observations, but by wide-spread and lengthened series of observations of the meteorological appearances which precede meteorological changes. And to this subject the Society has devoted a reasonable share of its attention, by offering a prize for the best Essay on Weather Prognostics.

But Mr. Newnham must speak for himself; the following is his illustration, somewhat in Hindoo phraseology, of the advantages of *applying astronomy to Agriculture* (!). It may sound sensibly enough to the ears of those who have lived long in tropical climates, and who look for the annual changes of the weather as regularly as for the months which there they severally characterise; but to English ears it certainly appears to be sufficiently ridiculous.

"Neighbour, let us discuss according to our atmospheric tables the probable season to come. In *Taurus* (April), we had excessive drought. In *Gemini* (May), we have had nipping cold and lofty continuance of dry easterly wind; what sort of season do these anomalies portend in *Cnab* (June) for sowing the Swedes? or what may be their effects on the coming harvest?—

the markets?—the sowing time? Shall we thrash out our Wheat now, or lay by awhile for a better price?"

If these questions had been or could be accurately answered by Mr. Newnham's oriental astronomy, his advocacy of its agricultural applicability (!) would be reasonable enough. But so long as this is impossible, we cannot but see an inconsistency in his setting himself up as the defendant of practical men and the advocate of practical measures, against a Society whose motto is "Practice with Science," and in his at the same time suggesting and enforcing the plausibility of ideas which are amongst the most visionary that ever were broached.

We agree with Mr. Newnham in the fifth reason which he gives for withdrawing from the Society, although we think it altogether insufficient to justify that step. He objects to the expensive encouragement of the pure breeds of cattle and sheep which is given by the Society in their Annual Shows and Premiums. However much good in this respect may hitherto have been done by the patronage of Societies and wealthy individuals, we think that the further improvement of animals for the dairy, feeding-stalls, &c., may now safely be left to individual enterprise, and that the income of the Society might now be more exclusively devoted to the improvement of cultivation-proper, by the diffusion of sound information on the subject, or perhaps by the establishment of example farms in the various districts of its connection.

In taking our leave of this pamphlet, we may safely assert that Mr. Newnham by its publication has failed in justifying the charge of impolicy, which he seeks to bring against the English Agricultural Society.

Miscellaneous.

Potato Failures.—In last week's paper we had the pleasure to copy from a Scottish cotemporary a report, amongst other matters, of the highly interesting discussion which took place at one of the forenoon meetings of the Scottish Agricultural Chemistry Association, in Glasgow, on the subject of Potato failures. This meeting had been announced for some time, some very eminent agriculturists attended it, and nothing can better show the exceeding difficulty of the question mooted—viz., What is the cause of the Potato failures, and is there a remedy for them?—than the discrepancy of opinion advanced on the occasion. The general opinion of scientific agriculturists appears to be, that there is a liability inherent in every plant which has for a long period been cultivated in the same soil to become deteriorated, hence the universal belief in the advantage of changing the seed; and that, in the case of the Potato, the most likely means of avoiding failure would be to procure a new generation of plants from seed (not tubers) of a healthy crop; but in the discussion to which we are referring, Mr. Girdwood's experience gave the death-blow, *in limine*, to this cherished opinion; the seedlings (whether raised from a healthy or tainted crop is not stated, however) were found to be as liable to decay as any others. Plant your Potatoes whole, and in the autumn, use only such seed as have the eyes plump, protect from frost, and, says Theory, you will have no failures; not so fast, says Mr. Burnet, of Gadgirth, I have done all this, and still have experienced failures. Mr. Alexander, of Southbar, had never witnessed a failure in early-planted Potatoes; how many, within a few miles of Dublin, would give a great deal to be able to say the same truly; why early-planted Potatoes are the most liable to failure; and as to this gentleman's other statement, that the failure of Potatoes is traceable to some ill-treatment, especially by stowing them in large masses, did it not occur to him that, up to 1832, no failures were caused by such treatment! Mr. Allison, of Mears, stated that Potatoes taken from those which, for two seasons, had not been cut, would not fail; it is, we fear, mere assertion; whole Potatoes, although not so liable to failure, we believe, as cut ones, still, it is notorious, do fail. Mr. Anderson, from the north of Ireland, as appears from his statement, has been most successful in his efforts to avoid failures; and the means he adopts, viz. liming the ground, planting only in drained land, pulverising the soil well, and not leaving either the manure or seed exposed to the effect of the sun and wind, are based on sound practical knowledge: his experience, however, that Potatoes which have been prevented from blossoming are not less liable to fail (if that were his meaning), does not accord with that of some of our correspondents; nor with that of others, if it be that Potatoes so divested do not yield larger crops. Mr. Andersen's experience, however—if he be, as we suspect he is, the excellent and practical land-agent of Sir Robert Fergusson, Bart.—at least since the commencement of the Potato failures, has been in a mountain district; where, it is well known, Potatoes are not so liable to fail as in lowlands. The successful practice of Mr. Reid, as mentioned by Sir Robert Bateson, Bart., of raising Potatoes intended for seed before they are quite ripe, and leaving them on the ground to be dried in the sun, although Professor Johnston declared that he had never heard of it, is known and practised successfully by almost every gardener with his Ash-leaved kidneys intended for forcing. And as to Mr. Fleming's experience—that the Cup Potato does not fail—we can only say, that such is not the experience of the farmers of this country. This discussion was, in fact, an epitome of the innumerable essays which for the last twelve years have appeared on the subject of Potato failures; and which may be resolved into this, that we are utterly ignorant of the cause of these failures, and that our only chance of avoiding them is to use mountain-grown—which often means unripened—seed which has been preserved from heating in narrow pits—to plant in dry, deep soil, in a moist time, using moist manure, and not permitting the sets to be exposed—even for a few minutes—to the parching effects of sun, or harsh wind.—*Dublin Farmer's Gazette.*

Threshing Machine.—There is now in operation at Twarnhayle experimental farm, belonging to S. and R. Davey, Esqrs., a threshing machine, which, from its simplicity of construction, and its great power, is a vast improvement on the former threshing machines, or those now generally used. It performs the work of three horses, and threshes 125 sheaves of Wheat and 225 sheaves of Barley or Oats in an hour; and this is performed by a poor pony of 13 hands high. The inventor is a miner, named Michael Harris, a poor man residing at Silverwell, in the parish of St. Agnes, who is possessed of surprising natural genius, and therefore deserves support. He carries the whole apparatus about in a small cart, and contracts with the farmers of the neighbourhood at per 100 sheaves. Several gentlemen have seen the machine, and pronounced it to be the greatest improvement yet made.—*West of England Conservative.*

Notices to Correspondents.

CHICORY.—*A Beginner.*—See *Gardeners' Chronicle* of May 11th, where you will find that the land should be cultivated as for Turnips, and 2 lbs. of seed per acre, sown in the end of April on ridge-drills, in rows alternately 16 and 4 inches apart. The plants should be singled out to 4 inches apart, and they may be harvested in November, when an average crop will weigh from 3 to 5 tons per acre.

DAIRY PRODUCE.—*A Constant Reader* will feel greatly obliged by any of our correspondents giving a rough estimate of the number of cows required to produce, per annum, 29 cwt. of butter, 12 cwt. of cheese, 1000 gallons of milk, and 80 gallons of cream; and likewise of the quantity of land necessary to *stall-feed* the said stock. A cow will, in ordinary circumstances, produce 2½ cwt. of butter per annum, or 3½ cwt. of cheese.

MANURE TANKS.—*Omega.*—If your liquid-manure has its volatile parts fixed, you may economically apply it to Grass land in winter; if its ammonia be not fixed, you had better make use of some fixer, or wait till spring before applying it. When once its ammonia is fixed, no fermentation in the materials with which it may be mixed will effect its release.

MOSSY LAND.—*T. D.*—The application of lime is said to be sometimes successful in eradicating Moss.

PARISH RATES.—*Querist.*—By the Parochial Assessments Act, passed in 1836, the rate for the relief of the poor must be made "upon an estimate of the net annual value of the several hereditaments rated thereunto, viz., of the rent at which the same might reasonably be expected to let from year to year, free of all usual tenants' rates and taxes, and tithe commutation rent-charge, if any, and deducting therefrom the probable average annual cost of the repairs, insurance, and other expenses, if any, necessary to maintain them in a state to command such rent." A form of Rate, containing amongst others, columns for the "Gross estimated Rental" and "Annual Value," are given in the Schedule to the Act. It would not be practicable to give an explanation of this ill-worded section in a short space, and we therefore refer you to an Instructional Letter of the Poor Law Commissioners on the subject, published in their third Annual Report, Appendix A, page 92, where the mode in which the net annual value should be estimated, and the distinction between gross and net rent are explained and exemplified. In the instances of assessment given by you there must, from some extraordinary circumstance, have been a great change in the annual value of the property, or the valuer must, at one of the two periods mentioned, have entirely lost sight of the provisions of the above-mentioned Act. Saleable underwoods only are rateable, and not timber.—*W.*

RED CLOVER.—*A Dairy Farmer.*—It is rarely economical to sow Red Clover without a Corn crop. From 6 to 12 lbs. of it are generally sown per acre in April along with the Barley. Two or three cuttings may often be had before the ground be ploughed up in autumn. You may do what you like with these cuttings, but you can rarely get more than one made into hay.

STEEPS.—*A Subscriber.*—We have not forgotten. Sulphate of soda has been found a useful manure for Potatoes. We shall be glad to know the results of your experiments.——*V. V. V.*—Professor Johnston recommends as a steep for Corn and Beans, phosphate of soda, sulphate of magnesia, nitrate of potash, common salt, sal-ammoniac or sulphate of ammonia; a mixture of 1 lb. of each in 10 gallons of water to steep 300 lbs. of seed—we presume for about twenty-four hours: the seed to be taken out and dried with gypsum or quicklime, and immediately sown.

TULL'S SYSTEM OF CULTIVATION.—*Omega* suggests that the effect of a thorough cultivation, such as Tull recommended, is similar to that of what is termed root-pruning; the effort of both being to induce a plant to draw its nourishment from deeper sources; and the benefits derived from the practice of the former system he attributes to the plant thus living upon warmer food. The chief advantages of the system consist, we apprehend, in the plant being enabled by it to lay hold of all the vegetable food which does exist in the soil, in the air being allowed to permeate the soil, and in the destruction of weeds.

*** As usual many communications have been received too late.

Pigs	3	4	4	0			

Beasts, 3462; Sheep and Lambs, 25,010; Calves, 120; Pigs, 220.

Our supply of Beef is rather shorter to-day, and of the best qualities there is a is manifest deficiency, fully two thirds of the quantity being little better than stores; in consequence, we have an advance of quite 2d per 8 lbs. on the first-rate Beasts; second quality are a very heavy trade, and some third rate are hardly to be disposed of. The supply of Mutton keeps steady, but the demand is rather increased to-day; we have a numerous attendance of buyers, at a little more money; some of the best Downs make rather over, and some of the best Longwools rather less than 4s, per 8 lbs; Half-breds are a little more saleable than last week, but not much in demand. Very little is doing in the Lamb trade. Veal and Pork are very heavy.

FRIDAY, Sept. 27.

We have rather too many Beasts to-day for the demand, amongst which we notice about 80 Dutch, in very good condition; the trade has suffered a decline of fully 2d per 8 lbs; the best Scots, &c., cannot be quoted at more than 4s, and the best Short-horns 3s 10d per 8 lbs. The Mutton trade is also very heavy, the dead markets having been very dull since Monday; we cannot, however, make any alteration in our quotation from Monday's exceptions 3s 8d to 4s for the best Downs, and 3s 8d to 4s 10d for the best Longwools. Lamb about the same. Calves are shorter, and the best quality might about 4s 6d. Pork trade is very heavy at late rates.

Beasts, 872; Sheep and Lambs, 8100; Calves, 280; Pigs, 220.

HOPS, FRIDAY, Sept. 27.

The Hop Market continues very active for both new and old Hops; the duty is stationary at 120,000*l.* The supply of fine coloured samples is very short, and they are eagerly sought after at high prices, the present currency is as follows—

Mid & Best Kent Pocks.	6	0	to	8	0	Sussex, Pockets	6	10 to 7	0

			,, Inferior	—	—	

COVENT GARDEN, Sept. 26.—The market continues to be well supplied, particularly with the various kinds of autumnal fruit, but trade is not brisk. Among Pines we observed several handsome specimens of the Queen and Providence. Black Hamburgh Grapes are very fine, and these, as well as other sorts, are sufficient for the demand. Pears are fetching a better price than they did last week. The Marie Louise and Brown Beurré bring from 5s. to 6s. per half-sieve, and good samples of Louise Bonne and Gansel's Bergamot are offered at from 4s. to 10s. per half-sieve. Apples have not varied since our last report. Among Plums, Coe's Golden Drop and the Imperatrice are tolerably abundant. Damsons are somewhat scarcer, and are also a little advanced in price. Peaches still continue good, and are sufficient for the demand; but Nectarines are scarce. Filberts are also very scarce. Of Walnuts there are plenty, they bring about the same prices as last week. Oranges are scarce. Lemons are tolerably abundant. Vegetables are, generally speaking, good in quality. Celery is very fine. Cauliflowers and Broccoli are also good; they have not altered in price since our last report. Some Brussels Sprouts have just made their appearance. Cabbages, Carrots, and Turnips are plentiful; and French Beans still continue to be well supplied. Onions are good and plentiful; and Endive, Lettuces, and other salading are tolerably abundant. Among cut Flowers we noticed Mandevilla suaveolens, Gladiolus psittacinus, Amaryllises, Jasmines, Camellias, Heaths, Pelargoniums, Fuchsias, Carnations, and Roses.

FRUITS.

Pine Apple, per lb., 2s to 5s		Figs, per doz., 2s to —s	
Grapes, Hothouse, p. lb., 1s to 2s		Filberts, per 100 lbs., 90s to 100s	
— Spanish, per lb., 1s to 1s 6d		Walnuts, per bushel, 16s to 20s	
— Portugal, per lb., 1s to 1s 6d		Oranges, per dozen, 1s 6d to 3s	
Melons, each, 1s to 2s		— per 100, 10s to 24s	
Peaches, per dozen, 2s 6d to 5s		— bitter, per 100, 8s to 20s	
Apricots, per doz., 1s to 2s		Lemons, per dozen, 1s to 2s	
Plums, per half-sieve, 2s 6d to 5s		— per 100, 6s to 14s	
— Imperatrice, per punnet, 1s 6d		Almonds, per peck, 6s	
— Coe's Gold. Drop, p. pun., 1s		Sweet Almonds, per lb., 2s 6d	
Damsons, per half-sieve, 1s 6d to 2s 6d		Cob Nuts, per 100 lbs., 60s to 80s	
Apples, Dess., per bush., 2s 6d to 5s		Nuts, Barcelona, 22s

Pears, Dess., per hf.-sv., 2s 6d to 10s		— Cob, 14s	

VEGETABLES.

Cabbages, per dozen, 6d to 1s 2d		Garlic, per lb., 4d to 6d	
Cauliflowers, per doz., 2s to 5s		Onions, per bunch, 3d to 6d	
Broccoli, per bundle, 6d to 1s		— large, per bushel, 2s to 4s	
Sorrel, per hf.-sieve, 6d to 9d		— Spanish, per doz., 2s to 4s	
Artichokes, per doz., 1s to 2s		Shallots, per lb., 6d to 8d	
French Beans, p.hf.-sv., 2s to 3s 6d		Tomatoes, per half-sv., 2s 6d to 3s 6d	
Scar. Runners, per hf.-sv., 1s to 1s 6d		Capsicums, Ripe, per 100, 4s to 6s	
Potatoes, per ton, 50s to 60s		— Green, per 100, 1s to 2s	
— cwt., 2s 6d to 3s		Radishes, per doz., 2d to 1s 6d	
— bushel, 1s 6d to 2s 6d		Lettuces, per score, 6d to 1s 6d	
— Kidney, per bsh., 2s to 4s		Celery, White, per bunch, 3d to 1s 2d	
Turnips, per doz. bch., 1s 6d to 4s		— Red, per bunch, 1s to 1s 6d	
Peas, per bushel sieve, 2s 6d to 4s		Endive, per score, 1s to 1s 6d	
Red Beet, per doz., 3d to 1s 6d		Mushrooms, per pottle, 1s 6d to 2s 6d	
Carrots, per doz. bchs., 2s to 6s		Small Salads, per punnet, 2d to 3d	
Basil, per bunch, 6d to 8d		Watercress, p. 12 sm. bun., 3d to 6d	
Horse Radish, per bundle, 2s to 6s		Parsley, per doz. bunches, 1s to 2s	
Savory, per bunch, 3d to 6d		Tarragon, Green, per bunch, 6d to 8d	
Cucumbers, Frame, each, 2d to 9d		Green Mint, per bunch, 2d to 3d	
— Ridge, doz., 2d to 3s 6d		Marjoram, per bunch, 2d to 3d	
Vegetable Marrow, per doz., 4d to 1s		Chervil, per punnet, 3d to 4d	
Spinach, per sieve, 1s 6d to 2s		Chilis, per 100, 1s 6d to 2s	
Leeks, per bun., 2d to 3d			

MARK-LANE, MONDAY, Sept. 23.

THE supply of Wheat from the home counties this morning was small, particularly from Essex; picked samples met a ready sale at fully last week's prices, damp and inferior descriptions sold slowly at late rates. Foreign was in more general request, and commanded our extreme quotations.—Malting Barley must be written 1s. lower; Grinding qualities are unaltered.—Old Beans maintain their late value.—New and all kinds of Peas are 1s. cheaper.—The Oat-trade is heavy, and barely supports the prices of last Monday.

FRIDAY, Sept. 27.

The arrivals of English Corn since Monday have been moderate; those of Foreign are good. English Wheat meets a free sale at Monday's prices, and Foreign, particularly fine qualities, finds buyers for retail quantities on fully as good terms as on that day. Good Dantzig in bond, and low qualities of Red, are inquired after for exportation to France, but we did not hear of anything being done.—Barley fully maintains its late value, and there appears more disposition to purchase both Malting and Grinding qualities.—In Beans and Peas there is no alteration.—The Oat-trade is firm, and needy buyers are compelled to pay very full prices.

Sales by Auction.

SIX DAYS' SALE OF VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition, by Auction, at the American Nursery, Leytonstone, Essex (about one mile from the Railway Station, Stratford), on Monday, 21st October, 1844, and five following days, at 11 o'clock, (to close Executors' accounts), the celebrated NURSERY STOCK, consisting of the choicest kinds of Fruit and Forest Trees, fine Evergreens, Ornamental, Deciduous, and American Plants, of every variety, in considerable quantities, and lotted to suit every description of purchasers. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their grounds, from its having many rare specimens that are only to be found in first-rate collections (also of the Trade, from its excellence), and comprising several thousands Azaleas, Rhododendrons, Ledums, Andromeda, all in fine condition for potting, being well furnished with bloom buds.

N.B. The ground is proverbial for safety of removal, the mould adhering to the roots. May be viewed prior to the Sale. Catalogues, One Shilling each, returnable to purchasers, may be had of the principal Seedsmen in London, at the Auction Mart, and of the Auctioneers, Leytonstone, Essex.

NURSERY STOCK.

TO BE SOLD BY AUCTION. By MR. J. KING, on the Premises, Acre-lane, Brixton, on the 14th Oct., 1844, and following day at 11 each day, the property of Mr. Dawson; consisting of a collection of Evergreen and Deciduous Shrubs, a large stock of Fruit and Forest-trees, Camellias, and other Greenhouse Plants, &c. &c. To be viewed till the Sale; Catalogues on the Premises; Mr. CLERK, Seedsman, Bishopsgate-street; and of the Auctioneer, Hackney-road.

TO BE DISPOSED OF.—A Very Snug FARM, situate in Surrey, about 13 miles from London, comprising 200 Acres of Arable and Grass Land, in high condition; may be had at a very moderate rental, together with a neat Cottage Residence, and all necessary Farm Buildings.—For particulars apply to MESSRS. BROOKS AND GREEN, Estate Agents and Auctioneers, 28, Old Bond Street.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & C. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

WHEAT-SOWING.

GUANO; Genuine Peruvian, Bolivian, and Ichaboe, on Sale; also Potter's Guano, Gypsum, Sulphuric Acid, Sulphates of Iron and Copper, and all other manures. Synopsis of prices, and mode of use, on application, &c.—Apply to MARK FOTHERGILL, 46, Upper Thames-street.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;

And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Sept. 27, 1844.

MANURES.—The Readers of the *Gardeners' Chronicle* must have noticed the complaints constantly made there of the Adulterations of Manures, and which are now carried on to a fearful extent.

The Advertiser, a Broker of the City of London, and in daily communication with several scientific Chemists, calls the attention of the Nobility, Agriculturists, and Farmers to his method of supplying Manures, by which a genuine article is secured. Each article is Analysed, and the Analysis forwarded to the purchaser, who can by this means obtain redress should the article differ from the Analysis.

Terms—cash and one per cent. commission for buying and forwarding.

A register will be kept of the Analysis of every cargo of Guano imported into London that is brought in the market.

Mincing-lane, London, Sept. 27, 1844:—

Bones .	£4 10s. 0d	Nit. of Potash p. cwt.	45. 6d

Nitrate of Soda, p. cwt.	0 14 0		

WM. NORRIDGE, 13, Rood-lane, Fenchurch-street.

POTTER'S GUANO MANURE is the only Guano that can positively be depended upon, and has stood the test of three seasons. The imported article, it is well known, is seldom twice alike, even when genuine, and is subject to a most extensive system of adulteration. Orders addressed early to the Works, 88, Upper Fore-street, Lambeth, will have instant attention. Testimonials will be sent per post, if required.

POTTER'S LIQUID GUANO may be had as usual of most Chemists and Seedsmen.

*** Beware of being imposed upon by inefficacious imitations.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE Attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 63, Dorset-street, Fleet-street, London.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSES of SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FIELD (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, in which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and purity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 54, Hawley-road, Kentish Town.

DRAINING OF LAND.

THE A LEVEL, designed for the Use of Workmen, in preserving a uniform fall in Drains and Water-courses. In consequence of the approval expressed and the demand made for these Levels at the recent Southampton Show, Mr. BAILEY DENTON has arranged with an eminent London Mathematical Instrument Maker to make them in any number required. Price 30s.

This Level is as accurate as a spirit-level, and so simple, that the workman unable to read can use it with facility. When closed it forms a 5-feet staff.

Orders addressed to Mr. DENTON, Land Agent, 9, Gray's Inn-square, London; or to Mr. CHARNOCK, Wakefield, Yorkshire, will insure a perfect instrument.

SEED WHEAT.

J. D. PIPER, of Colne Engaine, Essex, (Member of the Royal Agricultural Society), has been four years raising two new Stocks of Wheat, viz., Piper's "Thick-set," and "Colne Whitechaff Red." At the last Southampton Meeting two sheaves of these Wheats were exhibited outside (notice not having been given in time for their admission inside), where they produced much excitement, and 6d. per ear was offered for them. Last year, in the same field, side by side, the Piper's Thick-set grew eight bushels and a half, and the Colne Whitechaff Red five bushels and a half more per acre than the most prolific Wheat grown in the neighbourhood. Last autumn J. D. P. measured a quarter of an acre off his field, and dibbled the Thick-set in rows a foot apart, and one bushel per acre; and though the plant was partially destroyed by the slug in the winter, and a good sprinkling of self-sown Potatoes were left to grow, still the yield was 14 bushels and a half, being equal to 14 sacks and 2 bushels per acre. One person this year grew 15 sacks and 2 bushels, another 14 sacks, and another 13 sacks per acre. One parcel weighed 64½ lbs. per bushel. This is, perhaps, the stiffest-strawed Wheat in England, and is adapted for strong or hollow bottom ground, and is not likely to get laid. J. D. P. will send to London, or to any place within ten miles of Colne, carriage free, and he will be glad to receive a post-office order, or reference to some house in London for the money, with the order for the Wheat. When it is all sold, J. D. P. promises to inform the Public, by an advertisement in this Paper; but if he should get any post-office orders after it is all sold, he will return them. The price is regulated according to the yield. Thick-set, 15s. per bushel; Colne Whitechaff Red, 9s. per bushel. Samples of the above, both threshed and in the straw, may be seen at our Office. N.B.—J. D. P. advertised in the two principal papers in Essex, where the above Wheat was growing, in order that Agriculturists might see it and judge for themselves of the quality and quantity.

TO AGRICULTURISTS.

CAMPBELL'S CORN STEEPS.—The Material for Wheat is on Sale by the undermentioned Agents, at 2s. 6d. per gallon.

Notwithstanding the extreme drought of the last spring and summer, the results of the experiments, in very many instances, have been surprising, averaging a saving on seed, in the first instance, of 3s. per acre, and yielding a produce of 20 per cent. additional in straw, and 40 per cent. in grain. Had the season been more moist the result would have been at least double.

From Report of the Judges, Glasgow Cattle Show, Aug. 7, 1844.

"Among the remaining articles of the Exhibition (of Roots, Seeds, &c.), the Judges would direct attention to a series of specimens exhibited by Mr. James Campbell, of Dundee, consisting of various Grasses (they were Wheat, Barley, Naked Barley, and Oats), raised from Seed steeped in a Fertilising Liquid. These were contrasted with others which had not undergone the process, and were in all cases decidedly superior."

Agents:—Messrs. G. Gibbs, 26, Down-street, Piccadilly; Thos. Gibbs, corner of Half-moon-street, Piccadilly; and Edw. Purser, 40, New Bridge-street, London. W. E. Rendle, Plymouth Manure Company; J. Campbell, 5, Mersey-street, Liverpool; P. Bruce, Merchant, Hull; Crouch and Co., 60, Close, Newcastle-on-Tyne; W. F. Karkeek, Truro; John Mayer, High Offley, Staffordshire; George Griffith, Bewdley; J. B. Hiden, Warminster; Phillips and Whittem, Coventry; John Towers, Maidenhead; Samuel Waldie, Carlisle; John Rodway, Carmarthen; James Black and Co., Aberdeen; W. Campbell, Merchant, Wick; Wm. Cuthbertson, Printer, Annan; J. and D. Campbell, Thurso; Maxwell Dick, Irvine; Dickson and Turnbull, Perth; Drysdale and Co., Glasgow; Drummond and Sons, Stirling; Wm. Dalrymple, Cupar Angus; John Dykes, Kilmarnock; James Haldane, Lauder; J. Bell, Dundee; Thos. Kennedy, Dumfries; A. Kennedy, Thornhill; P. Lawson and Son, Edinburgh; Wm. Low, Forfar; A. M'Farlane, Kinross; John Ogg, and Shield and Co., Arbroath; Geo. Robertson, jun., Kirkwall; John Rae, Elion; A. Simpson, Macduff; A. B. Telfer, Ayr; Wood and Co., Stonehaven.

EXTIRPATION of the MEALY-BUG, THRIPS, &c.—These pests to Gardens can be readily and effectually extirpated without injury to the most delicate plants, by HERRMAN'S VEGETABLE DILUTUM, sold in bottles at 5s., 10s., and 20s. each, free of carriage to all parts of Great Britain.—Address, with a remittance, either to SAMUEL HERRMANN, Romsey, Hants, or Messrs. MAXWORTHY and MANLY, Nurserymen, &c., Hackney, who are the sole London Agents.

EXTIRPATION of all kinds of VERMIN.—Office, 59, King William-street, City, London.—MR. J. A. CRYER, practical chymist, patronised by Her Majesty the Queen, H.R.H. the Duchess of Kent, the Royal Agricultural Society of England, and the Corporation of the City of London, and by special appointments to the principal Courts of Europe, begs to inform the nobility, gentry, merchants, agriculturists, shipowners, and the public generally, that he continues to CLEANSE, by contract, from one to five years, every description of PROPERTY, of rats, mice, moles, weasels, moths, fleas, bugs, &c., and as a guarantee of the efficacy of his preparation, respectfully refers to the certificates of his great success at Buckingham Palace and Gardens, Windsor Castle, St. James's Palace, Frogmore Lodge, Carlton Club House, Mansion House, Newgate Prison, Tavistock Hotel, Brewers, Chester, and Galley Quays and warehouses in Lower Thames-street, the property of Joseph Barber, Esq., and many others of public and private establishments, which may be seen at the office. The preparations, which are free of poison or deleterious drugs, may be had as above, in pots and bottles at 5s., 10s., 20s., 50s., and 100s. each, with full directions, which must be used in proportion to the extent of premises infested, to successfully eradicate the vermin, and which can be applied without injury to property. Dwelling-houses cleansed from 1l. to 5l. per annum; mansions and estates from 10l. and upwards; ships, docks, warehouses, granaries, breweries, farms, wharfs, &c., in proportion. Caution.—None are genuine unless bearing the signature and seal "Joseph Anton Meyer."

J. R. AND A. RANSOME, Ipswich, have published a Descriptive Catalogue, with Cuts, of their AGRICULTURAL IMPLEMENTS and MACHINES, which may be had by post, the order being accompanied by six penny stamps.

SMITH'S FIELD and GARDEN SEED-DIBBLE, or HAND-MACHINE, for depositing all kinds of Seed on the various Soils, with the greatest accuracy and despatch.—This Machine is so simple in its construction and operation as not to be liable to get out of order, and can be used by men or women. It is easily set, so as to deliver the exact quantity of seed intended to be planted, into each hole made by the Dibble, at one operation, without any further care than supplying it with Seed, by the person using it, and will plant Turnip and Mangold Wurzel Seed, Wheat, Barley, Peas, and all kind of Garden Seeds. In Tin, 1l. 10s. each; or with Copper Box and Tube, 1l. 15s. each. Commission allowed to Agents.

These Dibbles may be obtained of Messrs. COTTAM and HALLEN, 3, Winsley-st., Oxford-st., London, through the agency of the principal Agricultural Implement Sellers in the United Kingdom; or from the Inventor, by letter to his address, inclosing a Post-office order for the amount.—RICHARD SMITH, Upper Hall, near Droitwich, Worcestershire.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING.

THE above Material has been used and approved by the Nobility, Gentry, and Agriculturists generally, as a Roofing and Covering to sides of Farm Buildings; its advantages are—Lightness, Durability, and Economy. Being a non-conductor, it has been proved an efficient Protective Material to Plants, and is now in use at the Royal Horticultural Society's Gardens, Chiswick. It can be had of any length, 32 inches wide, at 1d. per foot, super. A discount to the trade.

THOS. J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

TO LANDOWNERS, AGRICULTURISTS, BUILDERS, &c.

McKIBBIN'S Improved ROOFING FELT is peculiarly applicable as a substitute for Slate, Zinc, Tiles, and other articles used for Roofing, from its ECONOMY, LIGHTNESS, and DURABILITY.

The disadvantages attending other materials used in roofing, preventing, to a great extent many useful houses and sheds being erected or rendered waterproof, it is submitted that the improved Roofing Felt will in a great measure—and in some instances altogether—obviate them, and prove most serviceable from its lightness, durability, and impermeability to water and damp, in covering Houses, Cattle-sheds, Workshops, Ropewalks, &c., and for the sides, as well as roofs, of light structures for plants, being likewise a non-conductor of heat; besides its economy in repairs, the timber where it is used may be so light as to save its whole expense; it requires no other coping, and may be applied by any person of common ingenuity; being flexible and portable also, it is free from breakage, the expense of carriage is inconsiderable in comparison with slates, tiles, &c., and it is not liable to contraction like zinc.

Sold in sheets 32 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet), with printed directions for applying them, same as adopted at the Government Dock-yards and various other public buildings.

Orders will meet with prompt attention if addressed to H. C. BOWDEN, 18, East India Chambers, Leadenhall-street, London, or to the following agents:—Liverpool, Messrs. Grueber & Co., 11, Manesty-lane; Plymouth, Thomas Stevens, Esq.; Birmingham, William R. Loyd, Esq.; Sunderland and Newcastle-on-Tyne, Messrs. John Ritson and Sons; Hull, William Ward, Esq.; Bristol, Messrs. Moor and Hewitts; Ramsgate and Deal, Messrs. Edward Hodges & Co.; Whitehaven, William Todd, Esq.; Glasgow, Malcolm Carmichael, Esq., St. Enoch-square; Cork, Messrs. Richard Wallis & Co.; Belfast, Messrs. Grueber & Co., Dunbar's Dock; who have also on sale McKIBBIN'S improved SHEATHING, BOILER, RAILWAY, and other FELT.

*** The "IMPROVED ROOFING FELT" will be found much more durable than the Common Felt made in lengths, and not subject, like it or continuous sheets of other material, to be stripped by storm; it can also be more easily repaired, and from the simple mode of application recommended, the wet cannot percolate through nail-holes, being only fastened down at the overlaps.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S  ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row, London.

[illegible]

POLYTECHNIC INSTITUTION.—The [illegible] MICROSCOPE, an original OPTICAL [illegible] adapted to its application to Nature and Art, is daily [illegible] to LONGBOTTOM'S OPAQUE MICROSCOPE, the LEPTOSCOPE, and the ONY-HYDROGEN MICROSCOPE. The PICTORIAL ILLUSTRATION of the MICROSCOPE, from COLLINS'S ODE, with Vocal and Instrumental Music, to the first subject exhibited by the PROFESSOR, at a Quarter to Five o'clock in the Afternoon, and at a Quarter to Ten in the Evening. Dr. RYAN'S popular Daily Lecture is on POISONS and their ANTIDOTES, delivered at Half-past Three, and on the Evenings of Mondays, Wednesdays, and Fridays, at a Quarter to Nine. Professor BACHHOFFNER Lectures on the alternate Evenings. The Lectures abound in interesting Experiments. The HYDRO-ELECTRIC MACHINE, DIVING BELL and DIVER, &c. The Music is composed and conducted by J. WALLIS, Mus. Doc.—Admission, 1s. Schools Half-price.

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers as follow:—Cottage Pattern—1 Cover of 20 inches, 3l 10s.; 1 do of 18 inches, 2l 3s.; 2 do. of 14 inches, 4l. 8s., the set of 4, complete, 11l. 10s. ONLY. Double Dome Pattern—1 Cover of 20 in., 4l. 14s.; 1 do. of 18 inches, 3l. 12s.; 2 do. of 14 inches 5l. 5s.; the set of 4, complete, 14l. ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7s. 3d. per oz.; Queen's Pattern, 7s. 4d. per oz. Superior Watches and Fine Gold Jewellery, cheaper than any house in London. West's Hand-book, with 100 engravings and full of useful information, is just published, and may be had gratis, and post free, on application to T. WEST, Silversmith, 18, Ludgate-street, London.

HEALTH, LONG LIFE, AND HAPPINESS.—EXTRAORDINARY CURE OF SCORBUTIC HUMOUR.

I, WILLIAM WOOD, of Rockwell Green, in the parish of Wellington, Somerset, hereby certify, that for almost seven years I was afflicted with SCORBUTIC HUMOUR on my nose, with a continued discharge, rendering me almost unfit for society; I tried several medical men, and various medicines for curing the same, but all proved of no avail, producing no beneficial effect; at last I was persuaded to try PARR'S PILLS, and after taking two small boxes and part of a third, I was completely cured, and I now feel no pain or inconvenience as before. Many parties in the neighbourhood, and your Agent for Wellington, Mr. GARNER, can bear witness that my testimony is correct, and I wish it to be made known, that others similarly afflicted may be encouraged to try the same medicine, which under the blessing of God has proved so serviceable to me.

Witness my hand this 6th day of August, 1844. WM. WOOD.

In the presence of JOHN GARNER, Wellington.

From Dr. C. STRANN, 126, Fulton-street, sole agent for Brooklyn.—An instance of the singular efficacy of PARR'S LIFE PILLS, which merits particular notice, occurred in the person of a lady, residing at Brooklyn, of consumptive make, who had been afflicted for upwards of six years with very great and general debility, headache, flatulence, faintings, and all the effects originating in an impaired constitution. Country air was tried, but to little advantage. She complained of weariness and pain on the least motion: her bowels were sometimes constipated, and at others lax, and never regular. At this period, she was recommended to try PARR'S LIFE PILLS, when no less astonishing than true, before she had finished two boxes, an entire and perfect cure was the result. To such, nothing can equal this antidote, as it imparts tone and strength to the stomach, and operates so mildly, that the most delicate of either sex can take them with the greatest safety.

To T. Roberts and Co., April, 1844. Yours truly, C. STRANN.

These, and hundreds of other cases of DECIDED CURES, attested on the highest authority, and already published, occupy upwards of 180 pages of letterpress. These Testimonials are published periodically, and may be had on application at any respectable medicine vendor's. The cures, in many instances, were effected after all other means had failed, and they thus establish the claims of PARR'S LIFE PILLS, to being considered the best medicine in the world.

CAUTION TO THE PUBLIC.—Beware of Spurious Imitations of the above medicine. None are genuine unless the words "PARR'S LIFE PILLS" are in WHITE Letters on a RED GROUND, engraved in the Government Stamp pasted round each box. Sold by all respectable Medicine Venders.

IMPORTANT to the FASHIONABLE WORLD.—By far the most indispensable of all the graces that contribute to personal adornment is the Hair. Its recovery, preservation, and improvement are peculiarly concern the elegantes of our fashionable circles, and any information which will insure these desirable results will be hailed as an inestimable boon. The following extract from the letter of a respectable chemist in Bridlington will be read with the highest interest —

"A lady, a customer of mine, has found great benefit from the use of your Balm. About six months ago her hair nearly all fell off. I recommended her to try your Balm of Columbia, which she did. In the course of a few applications the hair ceased to fall off. Before she had used one bottle it began to grow very profusely, and she has now a very beautiful head of hair. "I am, gentlemen, yours respectfully,

"——, Chemist and Druggist, Market-place, Bridlington.

"To Messrs. C. and A. Oldridge.—March 18, 1844."

C. and A. OLDRIDGE'S BALM of COLUMBIA, changes the Hair to curl beautifully, frees it from scurf, and stops it from falling off, and a few bottles generally restores it to its; it also prevents baldness. 3s 6d., 6s., and 10s. per bottle. The other prices are genuine.

OLDRIDGE'S BALM, 1, Wellington-street, the corner of Wellington-street, Strand.

GARDENERS' BENEVOLENT INSTITUTION.—NOTICE IS HEREBY GIVEN that an Election for FOUR PENSIONERS on the Funds of this Institution will take place on WEDNESDAY, 22d Jan. next. All persons desirous of becoming Candidates are requested to send in their testimonials, &c. on or before FRIDAY, 1st Nov. next, after which time they will not be received.

Printed Forms may be had on application to E. R. CUTLER Secretary, 97, Farringdon street.

UNIVERSITY COLLEGE, LONDON.—Faculty of Arts and Laws, Session 1844-45.—The SESSION will COMMENCE on Tuesday, October 15, when Professor MALDEN will deliver an INTRODUCTORY LECTURE at Two o'clock precisely.

CLASSES.

LATIN.—Professor LONG, A.M.
GREEK.—Professor MALDEN, A.M.
HEBREW.—A Professor will be appointed before the opening of the Session.
ORIENTAL LANGUAGES.—Professor FALCONER, A.M.
ENGLISH LANGUAGE and LITERATURE.—Professor LATHAM, A.M.
FRENCH LANGUAGE and LITERATURE.—Professor MERLET.
ITALIAN LANGUAGE and LITERATURE.—Professor PEPOLI.
SPANISH LANGUAGE.—Teacher, Mr. GIL DE TEJADA.
GERMAN LANGUAGE.—Teacher, Mr WIPPICH.
COMPARATIVE GRAMMAR.—Professor KEY, A.M.
MATHEMATICS.—Professor DE MORGAN.
NATURAL PHILOSOPHY and ASTRONOMY.—Professor POTTER, A.M.
CHEMISTRY.—Professor GRAHAM.
ARCHITECTURE.—Professor DONALDSON.
GEOLOGY.—Professor WEAVER, F.G.S.
DRAWING, in ALL its BRANCHES.—Teacher, Mr. MOORE.
BOTANY.—Professor LINDLEY, Ph.D.
ZOOLOGY, RECENT and FOSSIL.—Professor GRANT, M.D.
PHILOSOPHY of MIND and LOGIC.—Professor the Rev. J HOPPUS, Ph.D.
ANCIENT and MODERN HISTORY.—Professor CESSAR, A.M.
LAW.—Professor CLARK, A.M.
JURISPRUDENCE.—Professor MARKBY, B.A.

Residence of Students.—Several of the Professors and some of the Masters of the Junior School receive Students to reside with them; and in the Office of the College there is kept a register of parties unconnected with the College who receive boarders into their families—among these are several medical gentlemen. The register will contain references as to respectability, terms and other particulars.

FLAHERTY SCHOLARSHIPS.

Flaherty Scholarships of 45l per annum will be awarded in the Session 1844-45, by Examiners to be appointed by the Council, to the best proficients among the Students of the College of two years' standing, under the age of 21 years, as follows:—A scholarship, tenable for four years, in Mathematics and Natural Philosophy, and an Extraordinary Scholarship, tenable for three years in Classics. The examination will take place between the 7th and 18th of January. A Scholarship will be awarded in January, 1845, for Classics, and in January, 1847, for Mathematics. Printed copies of the Regulations concerning these Scholarships may be had on application at the Office.

Prospectuses and further particulars may be obtained at the Office of the College.

F. S. CLARKE, Dean of the Faculty.
Oct. 1844 CHAS. C. ATKINSON, Secretary to the Council.

BAGSHOT NURSERY (late HAMMOND'S).

GEORGE BAKER, late of Knaphill, has to inform his Friends and the Public, that, under an agreement entered into in July last, he has become the tenant of the Bagshot Nursery Grounds, formerly in many years occupied by Mr. HENRY HAMMOND. Mr. BAKER, attending assiduously to the stock, gathering it together in quantities, and of greater variety than has hitherto been kept at this Nursery. All letters addressed to Mr. BAKER, Bagshot Nursery, Surrey, will be punctually attended to.

HAMILTON'S CELEBRATED BLEACHING COMPOUND, (never before sent out), for Bleaching Goods sent postage free on receiving a post office order for 10s. 6d. The last three years 1000 families in the vicinity of Manchester and Stockport have completely substituted this compound for vegetable varieties, 1000 families—21 to 31 inches by 24 inches in deep—to be obtained—21 to 31 inches by 24 inches in deep—to be obtained. Also his TRANSFER of the Public APPLE, GRAPE, and CHOCOLATE. An annual sum of 1000l. Prize 50l. May both be had of Mr. T. WILD, Three Towers-street, Hanover; J. HAMILTON, Thornfield, Stockport; or Mr. J. MARTIN, Colchester, &c, Aldersgate-street, London.—Oct. 5.

SPLENDID NEW HEAVY-EDGED PURPLE PICOTEE, WOOD'S "PRINCESS ALICE"

JOHN WOOD begs to announce that the stock of this superb flower is now ready for sale at 12s per pair, postage included. It has gained the following prizes:—At Cambridge Florists' Show, 1843, it was the 1st seedling, and the 1st heavy edged purple, at the same Show, in 1844, it took the premium prize, beating all the Picotees exhibited. At Huntingdon, 1843 it was 1st seedling and 1st purple Picotee, at the same place, 1844, it was 1st, 2d, 3d, and 4th, excluding every other flower. At Peterborough, 1843, it was the 1st seedling, took 1st pair of purple, and was in the best stand of six Picotees; in 1844, at the same Show, it took the 1st pair, and was again in the 1st stand of six.

J. W flatters himself that this statement precludes the necessity of further comment. Plants of the above may also be had of HYAST and M MULLEN, 6, Leadenhall street.

J. W has a few pairs of that splendid Pink, Garratt's "Queen of Roses," for sale, at 7s 6d per pair, his Catalogue of Carnations, Picotees, &c., may also be had on prepaid application, and those about to commence growing, he will supply as follows, if left to his selection.

THOMAS JACKSON, Kingston Nursery, Surrey, Oct 4

NEW PLANTS

MESSRS. VEITCH AND SON have now ready for sending out the two undermentioned beautiful New Plants, viz —

HIBBERTIA VIOLACEA. Strong plants at 63s It is figured by Dr LINDLEY, in the "Botanical Register" for August last, who there says—"The Hibbertia violacea is one of the finest things obtained from South Brazil. It has been imported by Messrs Veitch and Son, of Exeter, who received for it the Large Silver Medal at the Horticultural Society's Garden Exhibition in May last. It will doubtless prove a very easily cultivated Greenhouse Plant, and is certainly unsurpassed in beauty by blue-flowering shrubs."

CITTORIA FULGENS. Strong plants at 42s This plant was exhibited at Chiswick, in May, under the name of Centrosema species, and received the Knightian Medal. See Report in *Gardeners' Chronicle* for May 25. It is figured in "Paxton's Magazine" for July last.

Messrs. V. and Son have also to offer the following fine plants, viz. —

Achimenes picta	Gardenia Sherborniana
Allemanda grandiflora	,, tetrasperma
Barbacenia squamata Veitchia	Gesneria polyantha
Clerodendron lævifolium	Gloxinia Cartonii
,, splendens	Hindsia longiflora
Cyrtoceras reflexa	Inga pulcherrima
Echites atropurpurea	Lalleandia cultivars
,, hirsuta	Pentlandia cultivars
,, splendens	Pentlandia cultivars
Gardenia Rothmannii	Pentlandia cultivars
	Tradescantia chrysops, &c. &c.

N.B.—Messrs. V. and Son's Classical Catalogue can be had on application.—Exeter, Oct. 4, 1844.

CARNATIONS AND PICOTEES.

JOHN DICKSON, Florist, Newton, Surrey, has prepared for the growers of CARNATIONS splendid flowers of Gentlemen, doubting them to be of the finest varieties, with the names annexed, which may be had of the Nursery, and of Messrs W. Lucas & Wakeman, Covent Garden, after the 7th September.

TO FLORISTS, Nurserymen, &c. &c.

WANTED by Messrs. in the vicinity of London, for the Wholesale, a few ORDERS for Stores, Stamps post-paid, which payment terms, and all particulars, to C., 12, Pall Mall.

NEW AND VALUABLE PLANTS.

R. GLENDINNING respectfully begs to offer the following very desirable Plants:—

CLERODENDRON INFORTUNATUM, 42s.—This is by far the finest species of this genus yet introduced, a plant of which was exhibited by R. G. at the Chiswick Show, in June last, and awarded the Large Silver Medal as a New Plant. It flowers freely in a dwarf state, and will remain in flower in a cool greenhouse six months. It is figured by Dr. Lindley, in the Botanical Register for April, and in "Paxton's Magazine of Botany" for August last.

Achimenes picta, 7s. 6d
Bucklya Lindleyana, 7s. 6d.
Harpardesia spinosa, 10s. 6 .
Correa Gouchi, 3s. 6d.
Clerodendron splendens, 5s.
,, lævifolium, 5s.
Cyrtoceras reflexa, 10s. 6d.
Echites splendens, 42s.
,, hirsuta, 5s.
,, atropurpurea, 7s 6d.
Gardenia Rothmanii, 5s
,, Sherbournensa, 42s
Gesneria macrochiza, 10s. 6d,
*Gloxinia Cartonii, 5s
,, magnifiora, 5s.
,, bicolor, 5s.
Gonolobus hirsutus, 42s.
Hindsia longiflora, 7s. 6d.
Jasminum Sidwellianum, 5s.
Lasiandra cauthiana, 10s. 6d.
Pentas carnea, 3s 6d.
Physianthus auroreneus, 42s.; the flowers of this creeper are as large as Stephanotis, of a creamy-white colour, and sweet-scented.
Portlandia grandiflora, 10s 6d.
Rondeletia, 42s.; a most beautiful new species, with long yellow flowers, from Havanna.
Tacsonia mollissima, 5s.

* See the "Botanical Register" for August last, in which these are figured.

Chiswick Nursery, near London, October 1, 1844.

DOUBLE ROMAN and PAPER-WHITE NARCISSUS, 4s per dozen. The above Bulbs, the former of which is so justly esteemed for its early blooming and excessive fragrance, and the latter for its purity and elegance, have been just received at A. CORBETT'S, late Mr BARRON'S, Italian and Foreign Warehouse, 19, Pall Mall. Also Dutch Hyacinths, Crocus, Tulips, Anemones, &c. &c. Price Catalogues of which may be had per Post.

THE GREATEST NOVELTY EVER OFFERED TO THE PUBLIC.

RHODODENDRON JACKSONII.—This splendid new hardy Rhododendron is confidently recommended as the most beautiful variety extant; it surpasses in the colours of its flowers the richest Geranium, and is quite a new feature in this noble family. It forces well, is a free bloomer, and of dwarf habit. A truss of flowers was transmitted to Dr. Lindley, who pronounced it "a very compact and handsome variety, with "great richness" in its general appearance." See the *Chronicle* of the 6th April last, page 216, "*Rhododendron*:—*C. L N.*" To be sent out in March at 10s. 6d. each.

WM JACKSON and Co. beg also to call the attention of the Nobility, Gentry, and the Trade to the following rare and valuable Rhododendrons, all warranted true, at the very low prices attached. The plants are from seed, fine and strong, twice transplanted.

Rhododendron campanulatum, averaging 1 inch, 3s. per 100.

Hybrids

Between R. campanulatum and the scarlet arboreum, 2 in., 3l		p. 100	
,,	,,	and R. venustum, 1 inch	2l. p. 100
,,	,,	,, maximum	3l ,,
,,	,,	,, arboreum, 1 inch	2l ,,
,,	,,	,, Catawbiense, 1 inch	7l 10s ,,

Usual Discount to the Trade on the above.

Cineraria Celestial, No 1, 2s 6d. each; do. Fairy, No. 2, 2s 6d. each; fine plants well established. See Dr. Lindley's opinion in the *Gardeners' Chronicle* of April 6th, page 216, under the letters "*C L N*," and Advertisement of Aug. 24th.

WM JACKSON and Co. take this opportunity of stating that in consequence of the great success they have had in propagating the above beautiful Cinerarias, they have reduced the price, which will be applicable to all who have already favoured them with their orders, which will be executed next month, and plants given to compensate for long carriage.

Their new Catalogue is now ready (in which is a list of their fine white and scarlet Rhododendrons), and may be had on application. A remittance or reference will be expected from unknown correspondents.

Agents in London Messrs WHITLEY and OSBORN, Isleham Nursery, who have seen the plants.

Cross Lanes Nursery, near Bedale, Yorkshire, Oct 4

TULIPS, HYACINTHS, RANUNCULUSES, ANEMONIES, GERANIUMS, AURICULAS, CARNATIONS, and LILIUM LANCIFOLIUM.

H. GROOM, Clapham Rise, near London (removed from Walworth), by Appointment FLORIST TO HER MAJESTY, begs to recommend to the attention of the Nobility, Gentry, and Public his extensive assortment of the above Flowers, which, from the success he has had in their cultivation, he can offer at very moderate prices. He particularly wishes to call attention to the highly flattering remarks on his Exhibitions of Tulips and Liliums lancifolium this season, in the various papers. He is also desirous of reminding the Nobility, Gentry, and Amateurs, who may wish to add to their collections or ornament their pleasures with the beautiful flowers, that this is the best season to make a selection. The varieties of the splendid Lilium lancifolium are particularly adapted for parterres, &c. besides being quite hardy, they flower at a time when the Nobility and Gentry are at their country seats, and when flowers are so much valued. They only require to be known to be universally cultivated. Catalogues can be forwarded by post on application. Foreign orders executed.

CARNATIONS, PICOTEES, PINKS, AURICULAS, ALPINES, AND POLYANTHUS.

JOHN HOLLAND, FLORIST, &c., Market-place, Middleton, near Manchester, Lancashire, respectfully informs his friends and the Florists and Public that his extensive and choice collection of the above Florists' Flowers are now ready for sending out. Catalogues of which are now ready, and may be had on prepaid application.

Market-place, Middleton, Oct. 4.

TULIPS.—To be disposed of for £6, a BED OF TULIPS, of 47 Roots, with their Offsets, in three drawers; an equal quantity of Anemones, Ranunculuses, and Roses, well-arranged and true to name, such as Polyphemus, Cerise belle Amie, Chiffonne, &c. &c. Apply to EDWARD WOODTHORP, Furlong, near Bridgnorth, Salop.

LILIUM LANCIFOLIUM.—Flowering Bulbs of these most beautiful LILIES to be had at the following low prices; Lancifolium album . . 1s. each,
" punctatum . . 2s. "
" roseum . . 3s. "
of W. J. Myatt, Seedsman, 46, Cheapside, London.
Seed from the best varieties of IXIAS and SPARAXIS, at 2s. 6d. per packet.

CAMELLIA JAPONICA.

ROBERT LAWSON, Esq., of Tiverton, intends disposing of his stock of Camellias, which he has collected at much expense, and successfully cultivated for many years. They are in the highest state of health, and most abundantly set with blooming buds. Mr. L. disposes of them solely in consequence of their having become too large for his conservatory. They are as follow:—

			£	s.	d.
Reticulata,	from 7 to 9 feet in height,	a very fine specimen, quite healthy and green	10	10	0
Imbricata,	from 7 to 8 feet in height,	do.	5	5	0
"	" 3 to 4 "		1	10	0
Maxima	" 7 to 8 "	a magnificent plant	7	7	0
Chandlerii	" 6 to 7 "	a fine plant	5	5	0
"	" 3 to 4 "		1	10	0
Lady Hume's Blush	6 to 7 "	fine	4	4	0
Double White	6 "		3	3	0
" "	5 to 6 "		2	10	0
"	5 "		2	10	0
Invincible (Gray's)	5 to 6 "		3	3	0
Fordii	" 4 to 5 "	very fine	4	4	0
" "	2 to 3 "		1	1	0
Double Striped	5 to 6 "	fine	2	10	0
Anemoneflora Alba	4 to 5 "		2	10	0
Speciosa "	4 to 5 "		2	2	0
Woodsii "	4 "	fine	2	10	0
Warratah "	4 to 5 "	fine	2	2	0
Florida "	4 to 5 "		2	10	0
Corrallina "	3 "		1	5	0
Lawsonii "	2 "	new	1	10	0
Colvillii "	2 "		0	10	6
Donkelaarii "	2 "		0	10	6
Insignis "	6 to 7 "	very fine	2	10	0
Eclipse (Press's)	6 to 7 "		2	3	0

The Prices affixed are for the separate plants, of which not less than 3 can be taken together. If the whole are taken in one lot a considerable reduction will be made. Mr. Lawson will be happy to show them, or give any farther particulars that may be required.—Tiverton, Oct. 4th, 1844.

J. KERNAN begs to announce the arrival of his large and carefully selected Dutch, Cape, and other Bulbs of every description.
Finest named Hyacinths, old favourites, from 6s. to 12s. and 18s. per dozen.
Double red mixtures, different shades, 3s. 6d. per dozen.
Double blue, 3s. 6d. per dozen.
Double white, 3s. 6d. dozen.
Single; each colour, as above, 3s. 6d. per dozen.
Early Tulips, Narcissus, Jonquils, Anemones, Ranunculus, Iris, Ixias, Amaryllis, with all the new Lilies and good Herbaceous Plants, hardy and greenhouse, worth cultivating.
J. K. has also to offer, of this season's saving, some very choice seed—
From the finest named Calceolaria, 2s. 6d. per packet.
" " " Cineraria, 2s. 6d. "
" " " Heartsease, 2s. 6d. "
" " " Geranium, 2s. 6d. "
Scarlet Phlox Drummondii, 6d. per packet.
Schizanthus Hookerii, 6d. "
Intermediate Stock, 6d. "
By sowing the above this autumn a season will be saved.
With many other good Biennials and Perennials. Also, Myatt's new Deptford Pine Strawberry; Myatt's British Queen do.; Prince Albert do., Lady's Finger do., Keen's Seedling do. Old Pine do., &c., &c.
Dailey's Scarlet Admirable Rhubarb, the very best for early forcing. Giant Asparagus and Sea-kale Plants. Rivers's new Catalogue and Amateur's Rose Guide.
White Clover, Rape, Winter Tares, Rye, and Italian Rye-grass, for early green food. Catalogues may be had on application. All Mr. Rivers's Dwarf and Standard Roses may be ordered through J. K.
Carthy's and other new Budding and Pruning Knives.
4, Great Russell Street, Covent Garden, Oct., 1844.

SPLENDID NEW PLANTS.

JAMES CUTHILL begs most respectfully to announce that he has now ready to send out strong, healthy plants of the following:—Lisianthus Russellianus, 2s. 6d. to 5s. each; L. nigrescens, 5s. to 10s.; L. longifolius, 5s. to 10s.; L. corymbosus, 10s. each; L. glaucifolius seed, at 2s. 6d. per packet. J. C. has a splendid Yellow Lisianthus which will be sent out next year. A Treatise will accompany each order on the best method of growing the Lisianthus. Fine roots of the Prince of Denmark Scarlet Clove-scented Carnation, an excellent forcer, 18s. per doz.; Petunia ornatissima (Van Houtte), a fine pencilled lilac, 1s. each; also Fleming's Trentham Cabul Melon, which gained several prizes at Regent-street—the best-flavoured and most extraordinary bearer; three lights produced 86 lbs. first crop—40 the second; and is now bearing the third; 2s. 6d. per packet. Latter's Victory of England Cucumber, 2s. 6d. per packet; Cuthill's early improved Black Spine, very handsome, 2s. 6d. per packet, or the three for 6s. The trade supplied by the same of the above Cucumbers, by sending a money order on the Camberwell Post-office.—Letters directed to J. CUTHILL, Florist, Denmark-hill, Camberwell, London, will be immediately attended to.
N.B. The Lisianthus nigrescens can be seen in bloom 7 feet high, with upwards of 1000 blooms upon it, and will continue in flower till Christmas.
Strong Plants of the British Queen, and Keen's Seedling STRAWBERRIES in pots for next year's forcing can be selected out of 4000 pots.

MESSRS. TYSO AND SON, Wallingford, Berks, respectfully invite the attention of the Nobility, Gentry, and Public to their extensive collection of TULIPS, RANUNCULUSES, CARNATIONS, PICOTEES, PINKS, &c.
TULIPS.—In beds, containing an equal number of Roses, Bybloemens, and Bizarres, under names, arranged for planting.
1st Assortment.—A bed of 35 rows, or 210 bulbs, £ s. d.
including many extra fine new sorts . . . 25 0 0
A bed of 40 rows, or 280 bulbs, ditto . . . 35 0 0
2d Assortment.—A bed of 30 rows, including many
very fine sorts . . . 15 0 0
A bed of 40 rows, ditto . . . 20 0 0
Messrs. T. and Son beg to inform the cultivators of the Tulip that they intend letting out six rods of their splendid new Tulip "Polydora," a third row Bizarre, figured in No. 15 of the "Floricultural Cabinet." It was much admired when in bloom in and near London this season, when in bloom, and will be found to possess all the requisites of a fine show flower. Price 5s.
RANUNCULUSES.—Messrs. T. and Son having cultivated this beautiful flower with unparalleled success, are enabled to supply strong roots of their seedlings and other fine varieties, adapted for competition. They obtained first prizes at Chiswick, June 18th; at Surrey Gardens, June 15th; and at several provincial Exhibitions this season.
Messrs. T. and Son's General Descriptive Priced Catalogue may be had, Gratis, on prepaid application, inclosing two postage labels.

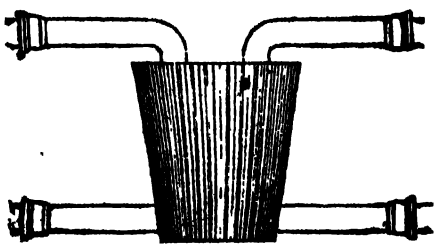
GEO. LIGHTBODY, Falkirk, respectfully informs the cultivators of the RANUNCULUS, that his CATALOGUE of SEEDLINGS is now ready, and may be had on application. A few Varieties of Superior New Seedlings will be let out this season.

NEW CARNATIONS, PICOTEES, AND PINKS.

MESSRS. N. and B. NORMAN'S CATALOGUE of SHOW VARIETIES can be had on prepaid application.—Bull Fields, Wrockwich.

SUNBURY NURSERY, MIDDLESEX.

J. T. WILLMER, Sen., begs most respectfully to offer to the Public that beautiful Purple Flake CARNATION "MAYO," which received a Certificate at the Horticultural Show of the Horticultural Society of London. Price 5s. 6d. per pair. Likewise a Carnation with buff ground, pink and maroon stripes; a novel and beautiful flower. 7s. 6d. per pair. The above Flowers are well adapted for bedding, when a sufficient stock is raised. The plants are well rooted and strong, with the rest of J. T. W.'s stock of Carnations, Picotees, Pinks, and Auriculas, Catalogues of which may be had by prepaid application, inclosing a postage stamp.—October 4, 1844.



MR. HOYLE'S NEW SEEDLING GERANIUMS.

WILLIAM MILLER respectfully announces to the Nobility, Gentry, Amateurs, and the Trade, that he has purchased the entire stock of the following superb SEEDLING GERANIUMS raised by G. W. HOYLE, Esq., of Guernsey, viz.:

		£	s.	d.
1844—Titus	each—	3	3	0
Pompey		3	3	0
Champion		2	2	0
These three for six guineas.				
1843—Unique		1	1	0
Queen of England		1	1	0
Claude		1	1	0
Sarah Jane		1	1	0
Amelia		0	10	6
Majestica		0	10	6
Rosalia		0	10	6
Flora		0	10	6
General Pollock		0	10	6
These nine for five guineas.				

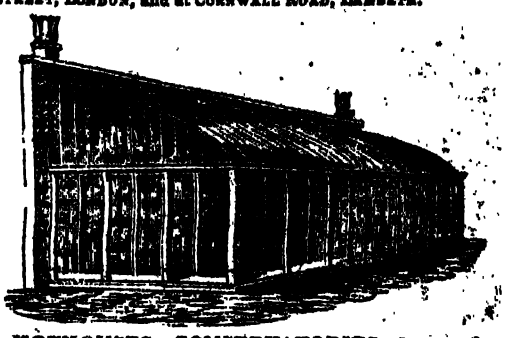
The entire set 10 guineas, with a discount of 20 per cent. to the Trade. A remittance must accompany the order from unknown correspondents.
Titus received a seedling prize at Chiswick, June 1844; Pompey, Champion, and Unique were pronounced by Professor LINDLEY, in the *Gardeners' Chronicle* of June 29, 1844, to be "three flowers of good substance, size, and variety;" and Mr. Glenny, in *Gardeners' Gazette* June 22, 1844, says, speaking of the Geraniums at the Chiswick Fête—"Mr. Hoyle had by far the best lot there; Pompey was the best of them, and Titus next." Blooms of the others were likewise exhibited at the June Fête, Chiswick, 1844, and attracted very extraordinary attention, and were universally admired. On the whole, the above varieties, for substance, roundness of form, and general excellent qualities, are among the best ever offered to floriculturists. Printed Lists, with full descriptions, can be had on application. The plants are now ready to send out.
Mr M. has been supplied by Mr. Hoyle with some choice GERANIUM SEED, which he saved from his own beautiful Seedlings, and the newest and best varieties sent out by other growers. Sealed packets of 100 seeds, 12s.; do. of 50 seeds, 7s. Also, Hybridised Seed, saved from his own extensive collection of Pelargoniums; packets of 100 seeds, 10s.; of 50 seeds, 6s.
Providence Nursery, Ramsgate.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.		Patent Door and Frames.	Fire-bars & Dead Plate.	Fire Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
in.	ft.	s.	s. d.	s. d.	s. d.		
10	1 5	20	7 6	6 6	2 6	30 feet.	12 to 20
Ribbed Boiler.							
10	2 2	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12	2 15	20	12 6	7 6	3 6	80 to 125 feet.	40 to 65
14	3 10	25	17 5	8 6	4 6	150 to 250 feet.	65 to 100
18	5 5	42	25 0	8 6	6 6	300 to 400 feet.	Warm a grapery 25ft. long, and a pit 20ft.
24	8 15	50	35 0	8 6	7 6	600 to 800 feet.	

If 2-inch pipe be used, one-third more. If 3-inch pipe, as much more.
The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.



CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SMEWIN, Ironmonger, Stevenage.
They may be seen in operation at Messrs. Chandler's, Vauxhall; Beddiges', Hackney; Henderson's, Pine-apple Place, Edgware-road; Rollisson's, Tooting; Pontey's, Plymouth; the Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

MR. LAWES' MANURES.—Mixed for Wheat, 7l. per ton; Super-phosphate of Lime, 7l. per ton. To be had of the Factory, Deptford Creek, near Greenwich; Super-phosphate of Lime, in a concentrated form, may also be procured at Messrs. WARNER'S, 24, Cheapside, in 7 lb. packets, price 1s.

HYACINTHS AND GREENHOUSE PLANTS.

HUMPHREYS'S SOLUBLE COMPOUND.—A few grains are effective. HALF A BOTTLE dissolved in a quart of water furnishes a superior LIQUID GUANO at half the usual cost. Sold in bottles, price 1s. 6d. each, by FLANAGAN and SON, Mansion-house-street; HURST and MCMULLEN, Leadenhall-street; W. CLARKE, Bishopsgate-within; SMITH, Islington Nursery; GRIMLEY and Co., Covent-Garden; HATT and RODLEY, 418, Strand; WILLIAM and JOHN NOBLE, Fleet-street; THOMAS GIBBS and Co., Piccadilly; SMITH, Covent-Garden; CHANDLER, Tavistock-row; W. J. NUTTING, 46, Cheapside; G. LAWRENCE, 18, Piccadilly; JOHN KERNAN, Great Russell-street, Covent Garden; LOCKHART, 156, Cheapside; SHUTTLEWORTH, Pantheon; MININ, ADAMS, and NASH, 63, Strand; THATCHER and SON, Islington; J. FRYER, Clarendon-terrace, Camberwell; THOMAS ARNELL, Camden Town; THOMAS WATKINSON, Market-place, Manchester; T. S. KING, Rochester; W. S. RENDLE, Plymouth; DICKSONS and Co., Edinburgh; PONTEY, Leeds; FISHER, HOLMES, and Co., Sheffield; P. LAWSON and SON, Edinburgh; J. THORNE, Shepton Mallet; and other leading Seedsmen in town and country. Wholesale Agents, DAVY, MACKENZIE and Co., 100, Upper Thames-street, London.

COTTAM AND HALLEN, ENGINEERS, IRONFOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.
HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.
Materials may be had for those who wish to fix their own Apparatus.
THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.
IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.
Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

Sales by Auction.

SIX DAYS' SALE OF VALUABLE NURSERY STOCK.

MESSRS. PROTHEROE & MORRIS will submit to Public Competition, by Auction, at the American Nursery, Leytonstone, Essex (about one mile from the Railway Station, Stratford), on Monday, 21st October, 1844, and five following days, at 11 o'clock, (to close Executors' accounts), the celebrated NURSERY STOCK, consisting of the choicest kinds of Fruit and Forest Trees, fine Evergreens, Ornamental, Deciduous, and American Plants, of every variety, in considerable quantities, and lotted to suit every description of purchasers. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their grounds, from its having many rare specimens that are only to be found in first-rate collections (also of the Trade, from its excellence), and comprising several thousand Azaleas, Rhododendrons, Leduma, Andromeda, all in fine condition for potting, being well furnished with bloom buds.
N.B. The ground is proverbial for safety of removal, the mould adhering to the roots. May be viewed prior to the Sale. Catalogues, One Shilling each, returnable to purchasers, may be had of the principal Seedsmen in London, at the Auction Mart, and of the Auctioneers, Leytonstone, Essex.

BUNNEY'S FINAL SALE.
TO NOBLEMEN, GENTLEMEN, NURSERYMEN, BUILDERS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor (in consequence of the Lease having expired), to submit to Public Competition by Auction, on the Premises, Kingsland Nursery, Balls Pond-road, on MONDAY, Oct. 7, 1844, and following days, at Eleven o'Clock each day without reserve, the whole of the valuable NURSERY STOCK, consisting of FRUIT and FOREST-TREES, a considerable quantity of EVERGREENS, AMERICAN PLANTS, STOOLS, &c. The Stock is particularly worthy the attention of Noblemen and Gentlemen laying out their Grounds; also the Trade, from its excellence, and comprising an excellent collection of Ghent AZALEAS, MAGNOLIAS, RHODODENDRONS, &c. May be viewed prior to Sale. Catalogues may be had on the Premises, of the principal Seedsmen, and of the Auctioneers, Leytonstone.

ISLINGTON NURSERY.
TO NOBLEMEN, GENTLEMEN, NURSERYMEN, and Others.

MESSRS. PROTHEROE AND MORRIS are instructed by the Proprietor to submit to Public Competition, on MONDAY, 14th October, 1844, and 2 following days, at 11 o'clock, (in consequence of the ground being required for building,) a portion of the valuable NURSERY STOCK, consisting of about five thousand Belgian Azaleas, in 40 fine varieties; several thousands fine Hybrid Rhododendrons, well furnished with bloom buds; Green and Var. Nellies, Chinese, and Siberian Arborvitæ, about five thousand Laurels, with a fine assortment of Fruit and Forest Trees, Flowering Shrubs, &c. May be viewed prior to the Sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, American Nursery, Leytonstone.

TO GENTLEMEN, FLORISTS, AND OTHERS.

MESSRS. PROTHEROE AND MORRIS are instructed by Mr. FRANKLIN (in consequence of his Lease having expired and the ground let for building), to submit to Public Competition, on the Premises, Cottage-place, City Road, on THURSDAY, October 17th, 1844, at 11 o'clock, the whole of his VALUABLE STOCK, consisting of named Seedling Tulips, Auriculas, Carnations, Picotees, and Pinks, Greenhouse and Hothouse Plants; a capital Greenhouse, 24 ft. by 11 ft.; and sundry Effects. May be viewed prior to sale. Catalogues may be had on the Premises; of the principal Seedsmen; and of the Auctioneers, Leytonstone.

SUPERB DOUBLE FULLYHOCKS.

WILLIAM MAY begs to announce that he is now prepared to send out his collection of the above splendid and showy plants, of all the various shades of colour, from black, or dark, to white. As his stock is large, he is enabled to supply them upon very moderate terms, viz., 4s. per 100.

N.B.—As this plant is becoming popular as a show flower, W. M. has a few very select varieties, by name and colour, at 2s. per dozen, which he has selected for the purpose of exhibition. Also Seed selected from finest double flowers, in packets, at 2s. 6d. and 5s. each, post-free. The above may also be had by order of the principal Seedsmen in London, and of Mr. WATKINSON, Market-place, Manchester. A remittance or reference from unknown correspondents.

Rose Nursery, Bedale, Oct. 4.

J. T. WILLMER, King's Road, Chelsea, by Appointment Florist to Her Majesty, begs to inform his Friends and the Public that his Carnations and Picotees are now ready for sending out, catalogues of which may be had on prepaid application containing a postage stamp.

The Gardeners' Chronicle.

SATURDAY, OCTOBER 5, 1844.

MEETING FOR THE FOLLOWING WEEK.

SATURDAY, Oct. 12 Royal Botanic . . . 4 P.M.

In Mr. HOARE, in his recent work on the VINE, has startled some of our friends by recommending them to make borders without earth, we can hardly fancy their amusement when they shall have read of his proposing to grow Vines with their roots upwards. One would as soon have thought of advising gardeners to walk with their heads downwards; yet so it is.

If, says our author, you give Vine-roots moisture, they will shoot upwards, and grow as well in that direction as they would downwards. This being assumed, it is proposed to take advantage of their good nature, in order to overcome the difficulties attending the cultivation of the Vine out of doors in these northern latitudes. It is not so much our short summers, or our moist climate, that hinders the ripening of the Grape, as the coldness of our springs, and the impossibility of warming our soil till late in the season. Our feeble sun acts too slowly on our chilly land. But if that land were fully exposed to the solar rays in small masses, it would become heated much sooner; and then, if the Vine-roots could be confined to those masses, the vegetation of the plant would be accelerated sufficiently to insure the full maturity of many kinds of Grapes.

Such being Mr. Hoare's mode of reasoning, though not his language, he proposes the following device, which has certainly the merit of originality. He recommends that hollow brick columns be constructed, to the height of five feet above the level of the soil; that a Vine be planted at their bottom, in the inside (but with its head through the brickwork), in such a way that its roots cannot go downwards; then, by filling up the column with prepared materials, the latter will be forced to travel upwards in search of food, which, from its receiving the sun's rays in all directions, will be always warm. At the same time the Vine branches will easily train spirally over the outside of such columns.

But how are the proposed materials in those columns to be kept moist? If the sun is always shining on them, will not their contents become dry as well as warm? And if dry, on what are the inverted roots to feed? Mr. Hoare provides against the risk of dryness thus—

"When the column is built up within three courses of its intended height, and the materials filled in exactly even with the brickwork, a course of whole bricks must be laid over *the entire surface*, taking care that those which rest on the materials are not to be laid on mortar, but merely jointed with it. This course being finished, the last two are to be formed with whole bricks laid flush with the outside, and with their inner ends slightly sloping towards the centre of the column, which will cause all the rain that falls on them to run towards it, and fall into the sunken hollow space that will be there formed by this circular ring of brickwork. The circular space, which will be about 18 inches in diameter, and 6 inches deep, is intended as a receptacle for all the rain that falls on the surface of the top of the column, which will filter through the single thickness of the bricks, forming the bottom of the hollow space, and thence be distributed by absorption throughout the whole mass of the inclosed materials, thereby supplying that moderate degree of moisture to the roots of the Vine, which contributes so advantageously to its nourishment and support. The column will now be complete. The sunken space at the top of it may, if desired, be filled with mould; and Mignonette, or any other annual flower of suitable growth, may be grown in it, and which, hanging pendently over the sides of the column, will present a very graceful appearance."

By this means all danger of dryness is effectually avoided. Mr. Hoare assures us that

"[illegible] simple contrivance of chambering the roots in[illegible], and the provision of the sunken water-table [illegible] top of the column outside, prevent the necessity of the slightest trouble being required in the management of the Vine beyond that of the ordinary routine of pruning and training; while, at the same time, the Vine is placed in such superior conditions with reference to its roots, that fine well-ripened Grapes may always be depended upon."

We hope he does not deceive himself. If the Vine will ripen with certainty under this mode of treatment the invention is one of the first importance, and the contriver will have deserved the grateful thanks of the country: but the proof is yet to come.

Knowing as we do the perseverance with which Mr. Hoare has prosecuted his inquiries into the habits of the Vine, how numerous are his experiments, with what care they have been conducted, and how perfectly trustworthy are his statements, we cannot doubt that he has good grounds for expecting success in this novel operation, and we therefore recommend the attempt to be made. A single season will test the value of column-growing; for if the Vine will grow well, it will probably ripen its fruit under such circumstances. There is no question about the roots going upwards if they are prevented going in the opposite direction; there can be no doubt that the Vine will grow freely enough in such a position. The difficulties in our mind are these:—1. Will the columns really furnish moisture enough? The powers of perspiration by the Vine are very great, and the loss of moisture thus occasioned is more considerable than we should have expected chambered columns capable of making good. 2. Will the Vine escape the attacks of the red spider, in this apparent deficiency of moisture? 3. Will it not be stimulated into growth so early in the spring as to be checked and blighted by our cold north-east winds and late spring frosts? 4. Will not the foliage, when it comes to cover over the brickwork, intercept the warm rays of the sun, and thus counteract the effects anticipated from column-growing? These are questions which theory cannot answer; their solution must be sought in experience, and in experience alone.

EVERY TULIP-GROWER is aware of the importance of getting a good strain of any given variety; for twenty breeders may come into colour, yet not more than one of that number shall be what is termed *a decided good break*.

We are often asked, What is the best method of breaking breeder Tulips? or, in other words, what means can be adopted to induce the flower to assume those variegated tints so highly prized by connoisseurs—*a clean feather or perfect flame?*

The general supposition is, that by frequently changing the soil, situation, &c. this desideratum may be attained. We agree that to a certain extent the bulb may be so far affected, that occasional *breaks* may result from adopting this plan. Still we think it may be accomplished in a much more certain and satisfactory manner.

Bulbs in a breeder or self state throw up stronger and bolder flowers than when *in colour*; the stems often decreasing in height several inches, assuming a sort of constitutional weakness (if we may so term it), when they become variegated. In fact, the broken flower is much less robust than its breeder. If, then, a deficiency of vigour will induce a bulb to put forth a feathered or flamed flower, instead of a plain or self-coloured one, by what means can this end be attained?

We imagine that taxing the resources of the bulb, weakening its energies, and reducing its strength, will have the desired effect; and to support our opinion we will adduce a case or two in point. Many years ago, when we thought less of cause and effect than we do now, we were much struck with a singular occurrence, bearing on these ideas. We planted a large bed of breeder Tulips; during their period of bloom they were much frequented by bees, which issued from the cups of the flowers, covered with farina, as black as sweeps. The impregnation of the flowers was completed; they formed perfect heads of seed, which were allowed to remain on till they were thoroughly ripe. The ensuing season the bulbs were planted as usual, and when the flowers expanded we were surprised to find that the whole collection, amounting to some hundreds, were, with very few exceptions, in a broken or variegated state. As it is usual to break off the capsules in order to strengthen the bulb, may we not infer that if the resources of the bulb are drawn upon to ripen a pod of seed, that it is consequently weakened and predisposed to alter its character, and assume those beautiful and varied markings so much desired by the amateur?

On another occasion a friend of ours planted some seedling breeders, the bulbs being in a very diseased and cankered state; the succeeding year he had a general break, and certainly there were some splendid flowers amongst them.

Another old experimentalist informs us, that many of his breeder Tulips break into colour, by allowing the bulbs to be exposed to all weathers, from the time of taking up to the period of replanting.

Now, as variegation in the leaves of plants may often be traced to weakness or disease, may not the same effect arise from the same cause, in the case of the Tulip? Here we have bulbs weakened by ripening seed, others in an unhealthy state when planted; whilst some were constantly acted on by rain, frost, sun, and wind, and in each instance attended with the same results.

We trust our Floricultural friends will act on these hints; as, from repeated successful experiments, we entertain no doubt of their success.—*W.*

ON THE CULTIVATION OF ASPARAGUS.

HAVING seen in the *Chronicle* lately, many inquiries respecting the culture of Asparagus, I beg to give an account of a mode by which I have always produced a very superior article—so much so, that it has almost invariably obtained the premier prize at Exhibitions.

I have hitherto planted the greater portion of my plants in single rows, about a yard apart. I have lately, however, reverted to my old plan of double rows, with a good alley between, as I find some difficulty in getting soil enough in the single-row system, to blanch and load it from the influence of winds, which do Asparagus much injury.

In my general plan for a systematic rotation of crops, my Celery-beds are selected for the new Asparagus plantation. My rule as to quantity to be planted is merely to keep up the stock, by planting an extent equivalent to what I break up to force. Celery-beds prepared in a special way, form a most eligible situation for the new Asparagus plantation, as the person who takes up the Celery leaves the ground ready for the Asparagus without farther trouble.

I grow some also in pigeon-hole pits for forcing; however, I always break up and force a common bed or two for the earliest—say through December and January, and then force the pigeon-holed pits, as those pits become weakened excessively by very early forcing—a whole series of buds in a progressive state being destroyed or paralysed at the removal of the covering after forcing; whereas, if forced later, those buds may by a slight covering of litter be saved.

With regard to preparation of ground, I will commence with Peas, which always precede Celery in my rotation; I appropriate a considerable plot for these, or in other words, I keep them together as much as possible for the sake of system; and having an even number of rows I make it a rule to sow two at a time, at the distance of from four to five feet, and these when picked and the haulm cleared away furnish space for a bed of Celery of about the same width. The Peas being removed, the ground is marked out for the Celery-bed, after what is termed the Scotch method. The bed is now excavated to the depth of a foot, and the soil thrown right and left and made compact; and now six or eight inches of half-decayed leaves and dung, chiefly the former, and which had been used as linings to pits or frames, is trenched in, at least a foot deep in the excavation. The surface is now covered once more with three inches of the best rotten manure, which when spread is forked in and duly mixed. The bed is now planted, and when taken up for use, the operation, with a little care, levels and leaves the bed right for planting the Asparagus when the period arrives.

There is, in my opinion, many wrong notions about the proper period of planting Asparagus. I invariably plant in May, or, in fact, when the Asparagus is what the market-gardeners term "in feather," that is, about six inches high. I have, by many years' experience, found this the best time; and, perhaps, one of the best proofs of it is, that I seldom or never lose a plant. This year I had my ground ready in the end of April, but the drought being very great, I was determined, if possible, not to plant until rain; the rain did not come until the middle of July, however, and tired of waiting, I had planted my Asparagus a fortnight previous. I watered it every morning, and a finer brood of plants were never seen—not even one missed; therefore, there can be no great danger attending spring planting.

In planting, the beds are set out for two rows each, the rows two feet apart, with an alley of four feet between them. The line being stretched precisely where the Asparagus is to be, a slanting cut is made sloping from the line, about nine inches deep, and the soil thrown out as in forming an edge for Box; the same cut is made on the opposite side of the line, leaving a sharp and angular ridge, across which the plants are set astride; the operator taking half of the roots in the one hand and half in the other, divides them across the ridge, at the distance of ten inches between plant and plant.

Previous to planting, however, some fine highly decomposed old vegetable matter is placed up the line, in contact with the roots, and pressed firm; the roots are slightly tipped, and dipped in a puddle of thick dung-water. My plants are usually two years old, for it is a waste of ground to plant earlier, unless in cases of emergency. I need scarcely add that the young plant must be watered every morning for a week, unless rainy.

The only treatment necessary the first year, at least through the growing season, is to keep them perfectly free from weeds. If any crop is planted between them, it should be a row of Coleworts from a June sowing, which would make their growth chiefly after the Asparagus had done its best.

In November, the ground is dressed with good rotten manure, and in spring the alleys are thrown over the manure, just deep enough to cover it. No cropping can now be carried on between the rows, although a good crop of Cauliflowers may be grown in the alleys. The

next point is the mode of dressing pursued in the autumn of the second year.

I hold it of much more importance to feed the Asparagus at the extremities of the roots in the alleys, than over the crown; good cultivators of it in brick-pits, do not allow the alleys, after forcing, to remain empty all the summer; they are filled with good rotten manures, and any one who has witnessed the emptying of these alleys in autumn, preparatory to forcing, must have been struck with the abundance of strong white roots, of which such alleys are full, and which are annually (it may be) cut off. Such roots can scarcely be produced from the crown: and it occurred to me some years ago, that the alley, above all, should be well attended to with manure. I *therefore* in November of each year, as soon as the ground is cleared of dead stalks and weeds, cause all the *loosest* of the soil to be drawn off the beds with a rake; the bed is then well dressed with very rotten *manure*, and left for the winter. In February the alleys are dressed about from six to nine inches thick, with *half-rotten* manure and leaves, from partially decayed linings, which is trenched down very deep, and the bed is then soiled, over the manure, to the depth of four inches, with fresh soil from the alleys. This completes the whole course of my mode of culture. Finding the plants much injured by winds, in the growing season, I have deemed it necessary to run lines of pitchcord up my principal rows, to support the stems, and this I find a great assistance.

My mode of cutting is similar to the market gardeners', excepting that after cutting about twice in the spring, I leave one stout shoot to each stool, with the intention of promoting the fibrous action of the root. As for the rest, I cut all that are of any size until about the end of May, when I cease cutting a bed or beds of my prime, which I now suffer to grow for the earliest cut in the following spring, continuing to cut from the rest until about the end of June.

I have only used salt for one season to any extent. I have much the same opinion of the mode of applying it that I have of liquid manure—little and often is my maxim. I quite agree with Mr. Bree, in a late Number of the *Chronicle*, that it would be very injudicious to apply it when the tender bud is arising. My plan has been to apply it at intervals, when the shoots are a yard high, giving a slight sprinkling in showery weather, three or four times in July and August.

I would particularly direct attention to the alley dressings of rather raw materials; and, whatever may be the merits of salt, of which I have a high opinion, Asparagus will always require abundance of manure in order to grow it fine. Salt and other inorganic matters can do little for the mechanical texture of the soil, which is a most essential thing in the cultivation of all plants.—*Robert Errington.*

THE ANTIQUITIES OF GARDENING.

No. II.—Extracts from Sir Thomas Hanmer's Manuscript on Gardening—1660, 1670. (*Continued.*)

"*Prices of July Flowers* received from George Ricketts, of Hogaden, London, 1667: Crown of Bohemia, Bride of Holland, Duchess of York, King of Assyria, Virgin of Middlesex, House of Commons, Belle Infanta, Tamerlaine, &c; all these are at 18*d.* the root, one with another."

"*Fruite-trees* had from Captaine Leonard Gurle, his nursery neere White Chappell Church, London, 1667. Two Wynter Bon Chrestiens, 3*s.*; two Wynter Bergamots, whereof one was Bergamot de Burgi, 3*s.* Orleans, Matchless, Damascus, and Prunello Plums, 1*s.* apiece. One White Nutmeg Peach, 4*d.* One Syon Peach, 5*s.* One Violet Musko Peach, 5*s.* Three other Peaches, 3*s.* each. One Elrug or Gurle's Nectoran, 10*s.*"

"*Vines*:—D'Arboys, Red Frontiniac, White ditto, Orleans, 2*s.* to 2*s.* 6*d.* the plant. A mat to lap them up in, 1*s.* 6*d.*; total, 3*l.* 6*s.* 6*d.* Many of these were much galled in the carriage down; but hee promised to abate what I thought good, and to make good what died the first year."

"*Gurle.*—I sent up from Bettisfeild to Gurle, by Smyth the carrier, or Johnson, 3*l.* to pay Gurle all due for the trees I had from him in wynter, 1667, which was paid him and I have his receipt. Hee was to send me this next wynter 1669, one tree of Gurle's Nectoran, and one lusty tree of Lord Mordant's Peach instead of these that died, and nothing more."

"*Among the Vines* received from John Rose, the King's gardener at St. James's Park, were the Lombardy, and another called the right Rhenish Grape by the King, and these two were much commended by him." 16 others plants of Vines are enumerated. "These 18 rooted Vines are to cost 12*d.* the root one with the other. I paid after for them. The *Lombardy Vine*, as Rose the King's gardener calls it, bears a fair red Grape, which the King loves. The Rhenish Vine bears a white longish Grape, very good, but must have a warm wall."

Mention is made of a Morillion Cherry; this was most probably a Morello; for the same occurs in the lists of trees planted against walls, together with a distinguishing property of the Morello. "Against the east upper wall in the Great Garden is planted one Orleans Plum from Sir Clus. Wolsley, then one Morillion preserving Cherry."

"*Plums.*—Monsieur is the same as that called in England the Orleans Plum, a faire, red, round Plum, comes clean from the stone, ripe betimes in August, a hardy tree and a good bearer." [Monsieur is syn. to the Orleans according to the Horticultural Society's list of fruits.]

"Cœur de Pigeon, a small reddish round Plum, very like to the Queen Mother Plum, if not the same." [They were proved to be the same after the lapse of 160 years, in the garden of the Horticultural Society.]

"*Vines.*—The true Raisin of the Sun bears a great long red Grape. The Rhenish Vine bears a white longish Grape, very good, but must have a very warm wall."

Home Correspondence.

The Horticultural Society.—I am surprised to hear that some people are complaining about the value of the prizes given by the Horticultural Society to fruit-growers. I have looked at the schedule lately advertised, and I must say a more unreasonable complaint could not be made. It is quite true that the large gold medal is not offered for fruit, although it is for flowers; nor might it to be. To say nothing of the difference in the cost of conveyance, which you have yourself alluded to, and which I understand is entirely defrayed for the fruit-growers by the Society, (that is very true, *Ed.*), does any gardener pretend to say that as much skill is required to produce five kinds of fruit, as forty kinds of stove and greenhouse plants? Why, if each sort of fruit requires a separate amount of knowledge of gardening, in order to be successful with it, so does each sort of flower; and therefore a collection of stove and greenhouse plants, containing forty distinct plants, will require eight times as much skill as five sorts of fruit. In this point of view the medal for the latter should be only 2*l.* 10*s.*, when that for forty plants is 20*l.*; and yet the Society gives 10*l.*, and is abused for it. It is very well for Mr. Henderson to think that nothing is like leather, but the public will not agree with him. In my opinion the fruit-growers showed their good sense in not putting in claims for higher rewards, as we learn from you was the case; the Society is as liberal in medals as it is proper to be, and it is very ungracious in those who profit by it to grumble, because it is not prodigal. Is there no such thing as honour to be gained by successful exhibition? and does Mr. Henderson think it is the cash, and the cash alone, that is worth striving for? I hope he has higher and less sordid motives. — *A-Looker-on.* [There seems no object in continuing this discussion; and therefore we here close it. The Society has made its decision for next season; and if the fruit-growers think they have anything to complain of, they should address themselves to the Vice-Secretary immediately after the Exhibition of next year. They may be quite certain that their suggestions will have full consideration.]—*An Exhibitor* adds, "In answer to Mr. Henderson's letter in the last *Chronicle*, you speak of half-a dozen van-loads of plants being brought to the Society's Exhibition, but you do not inform us that the person who sends them does not live two miles from the gardens, and that they gain as many medals as will bring the value of them at one Exhibition to 40*l.*, which an exhibitor of fruit cannot gain at the three, if he was to win the three first Prizes. Now, with regard to the fruit-growers, many who exhibit have 100 miles to bring their productions, and which they do at their own expense, and which expense often amounts to more than the value of their medals, if they are awarded any. I must beg to inform you that if you do not place the fruit-growers upon an equality with the plant-growers, you will soon lose their support.—[We print this leter *verbatim*, as a sample of the accuracy of persons like "An Exhibitor." It is notorious that the Horticultural Society pays the carriage of all fruit sent for exhibition, and returns it carriage-paid.]

Mode of taking Hives.—The discussion in which several of your correspondents have lately engaged concerning the best mode of destroying wasps' nests has led to a gentleman making inquiry of me, whether spirits of turpentine might not be used with effect in destroying bees when hives are taken. He states his reason for asking the question to have arisen from having remarked in several meetings of late for the encouragement of labourers, that the hives of honey exhibited by them had been much discoloured by their burning the bees. I can have no doubt that spirits of turpentine will kill bees as readily as wasps. If the hive were placed overnight above a small quantity of the spirit, I presume all the bees would be found dead or torpid before morning. The objection which occurs to me is the possibility of the odour of the turpentine flavouring the honey, though I think the effect would speedily disappear, and perhaps not be disagreeable. Entomologists are well aware that a bruised or chopped-up Laurel-leaf, when placed under a wine-glass, emits a sufficient quantity of prussic acid to destroy a wasp or fly in about two minutes. I remember the knowledge of this fact having been once applied to the taking of a hive. A quantity of Laurel-leaves were chopped up and placed in a washing-basin; the hive was then placed upon the basin over-night, and in the morning all the bees were found to have dropped into it, and were dead or stupified. A small quantity of prussic acid would probably be quite as effectual as the turpentine, and would produce no bad flavour. I have no experience as a bee-fancier, but I believe the wholesale slaughtering of this valuable and interesting insect has been shown to be unnecessary by the "Conservative Bee-keeper," and other writers on the subject. I have myself no fancies about not destroying bees for their honey on the score of cruelty. I cannot see how this act is more cruel than killing sheep for their mutton, or crabs for their claws. It is still the appointment of the present order of creation, "that the fear of us and the dread of us shall be upon all that moveth upon the earth, and into our hands they are delivered for food unto us." If, indeed, it can be shown that bees may be quite as economically deprived of their sweets by not destroying them, as they are by the more usual method, then I had much rather see their lives spared. But if the conservative system be not a strictly economical one to the thrifty cottager, its adoption had much better be restricted to the more acute sensibilities of the bee-fancier. —*J. S. Henslow, Hitcham.*

Potatoes.—The observations on the Potato, signed "R." in last week's Paper, are excellent; and it is to be hoped that some of the many Potato-growers who read the *Chronicle* will recollect them in their practice. In securing heaps of Potatoes for winter and spring use in the field or garden, the custom of putting straw next them is almost universal; but it is not the less wrong on that account. I know by experience of some years how much sweeter the tubers are when only coming in contact with the earth. The straw is wasted, and the Potatoes are injured, yet the practice will continue from unthinking habit, as we see daily and hourly in many other things. "R." says nothing on the greening of seed Potatoes. The drying of these that are watery or unripe, recommended in the latter part of "R.'s" paper, will be new to most readers, but is well worth trying. In the British Islands we have so many varieties and subdivisions of soil and climate, that all general rules have to be modified in practice. Thus the conflicting theories of Potato-growers might well puzzle the writer in the *Dublin Farmer's Gazette*, quoted at p. 602 of the *Chronicle* for this year. The facts stated seem to oppose each other; but Nature is always consistent—only man knows her means imperfectly, and must always be a learner. At a meeting of farmers in Scotland, they gave clearly the results of their varied experience, and one fact all the speakers seemed to agree in, which was, that seed Potatoes left in the earth where they grew, always produced a healthy crop. Several correspondents confirm this; and on mentioning it to an industrious neighbour of mine, he said that his father practised the same plan forty years ago, with uniform success. The Potatoes were always fresh and well tasted, and as seed they never failed; here we come to the simplest of all possible plans, for a very little extra earth will secure them from any English frost. Any one may see how certainly, after the most careful digging, many Potatoes show themselves in vigorous growth in the following summer. Regarding this important vegetable much is yet to be known, and much to be done. The immense crops considered possible by that great man, T. A. Knight, have not yet been realised, but there is no reason why they should not. One step towards this is the raising new varieties from seed. The very small produce of most early kinds surely need not be always so. Such difficulties have been overcome in gardening and farming, that this may be overcome also; and premiums ought to be offered by Horticultural Societies for new and valuable seedlings. Seeing some new kinds advertised by Mr. M. Smith, at p. 521, I procured a supply of the two last-mentioned sorts, which are, without exception, the finest early Potatoes I ever saw.—*S. H.*—*Lusor* adds,—In the Leading Article of last week is the following observation:—"It has, however, been found, that although Potatoes were taken up, and immediately stored in the earth in moderate quantities, with the mud so wet as to be dripping through the baskets, yet those Potatoes presented as dry an appearance when uncovered in spring, as others that were stored in a dry condition." This may have been the case, if the quantity was very small; but I would caution any Potato-grower from storing a large, or even a moderate quantity in a wet state. It is true that some of the white-skinned, or earlier sorts, may occasionally be stored in a wet state with impunity; but let no one attempt a trial with the red or later kinds. I write from repeated experience, having more than once had that part of the pit which was put together during a heavy shower, sink down into a deep hollow in the course of a few days, on opening which the whole of the Potatoes stored in that wet state were found rotten. These were Red Potatoes; the white kinds I have often stored in the same condition, and they have been uninjured."

Potato Failure.—If I may be allowed to suggest to the unfortunate who complains under this head (p. 645), I shall tell him, that though the season (too often blamed) may be in fault in some degree, his own treatment of his crop has favoured the failure. Thus, "the land is light, on gravel;" he does not state whether his stable dung was moist and decayed, or decaying, or whether put in, as most persons use it, in a dry undecomposed state. The description of land used being thirsty at all times, would this year be more so; the frequent libations of liquid manure most probably would be insufficient at any one time to reach the roots, while the evaporation from the ammoniacal compost used would yield an increase of nutrition to the stems and leaves. It is a well known fact, that even under common treatment, from an over manuring the stem or top being unusually luxuriant, no crop is expected from the roots which will repay the seed, and what there is, is generally, by forcing, large and bad. As in this season probably 16 weeks elapsed before rain or liquid reached the roots in this light soil on gravel, there would be nothing to induce the tuber-shoots to swell, if the plants had even then enough of nourishment to make them; all this time the tops were receiving unusual support, and making leaves instead of fruit. Frequent waterings in dry seasons nourish those plants effectually whose fruit is on the surface or above ground, but when tuberous ones are to be benefited by watering in a dry season, the earth should be well saturated with water till it reach the root of the plant to be acted upon, and this all gardeners know must be a large quantity to percolate from six to nine inches; the liquid manure may then follow, but to insure this reaching the root bed, another copious supply of water must immediately be poured in. To secure a vigorous

growth] of the Potato, roots should as necessarily be formed before the leaves, as should the roots of a hyacinth in glass or pot; for, if the top take the lead, it creates an eldest son in the Potato family, and the younger members are robbed by his drawing too hard upon their supplies, and, as in "R.'s" case, sometimes ruining the hopes of all to satisfy his useless existence and extravagant parade.—*A. W.*

Large Pines.—Will Mr. Mills be kind enough to answer the following questions, viz.—When were the suckers planted that produced the fine fruit recently cut at Gunnersbury Park? What has been the probable quantity of dung used to bring the fruit to maturity, and the probable expense for labour in applying the linings, &c.? and, finally, Is the flavour of the fruit grown in a moist dung pit equal to that grown in a more airy and dry situation? If Mr. Mills will answer these questions, it will oblige *An Admirer of well-grown Pines.*

The Dog-rose.—For the information of your correspondent relative to the Dog-rose (*Rosa canina*), p. 637, I beg to state that the fruit of this plant is invariably known amongst the vulgar in this part of the country by the name of Cankers, and the plant itself as the Canker-rose. I am unable to say from what cause it originally acquired this name, but I imagine that it might have arisen probably from the well-known Moss-like excrescences which so frequently occur on its branches, and are occasioned by insects. Many other plants are subject to attacks of a similar kind, and the diseases resulting therefrom are amongst our peasantry commonly, and I think not inaptly, known by the name of Canker.—*T. Bentall, Halstead, Essex.*

Wasps' Nests.—A gardener with whom I am well acquainted has had complete success this year in destroying wasps' nests, by simply pouring down the hole about half a pint of gas-tar in such a way as to smear it all round. This he does at any hour of the day when he chances to find a nest, as the wasps that are out are sure to attempt an entrance, and thus get besmeared and die, whilst those that happen to be within meet the same fate in their attempt to leave the nest.—*J. H.*

Polmaise Heating.—I imagine that the advocates of the Polmaise system of heating are wrong in ascribing the luxuriance of the Vines entirely to that mode of heating. May not a good border have something to do with it? Besides, it appears to me that very little fire-heat has been employed, as we have no mention of the Grapes being ripe until the 20th of September. I cut good Black Hamburgh Grapes perfectly ripened on the 30th of August last, to which no fire had been applied except for about a fortnight, when the Vines were in flower. I imagine that the Polmaise system consists in a good border, vigorous young Vines, a fine summer, with a little fire-heat, and good management, which I own are excellent means for producing fine late Grapes. But will it ripen good Grapes by the middle of April, which I have done by the use of hot water? If this has not been tried, I think it is premature to say that that system will supersede hot water and flues, at least for early forcing. I am induced to send the above, lest inexperienced Grape-growers should adopt the plan, thinking it suitable for general Grape-forcing.—*M. Henderson.*

Lisianthus Russellianus.—At the last meeting, in September, of the Cornwall Horticultural Society, held at Truro, there were shown two splendid plants of this exquisite flower. Upon the plant which was exhibited as a single specimen, and which obtained the first prize, there were upwards of 700 flowers in full bloom; and upon the plant which formed one of a collection, there were upwards of 500 blooms in perfection. These plants were raised and grown in a pit heated with hot water, and were generally managed as recommended by Mr. Cuthill, the successful grower of these lovely flowers. When the flowers began to expand, the plants were removed from the pit to a greenhouse, and were well watered every day, and occasionally they had doses of guano-water, which evidently strengthened the plants and acted as a stimulant in the expansion of the buds, until which they appeared to like. These plants were the admiration of every person who beheld them. Let those who wish to grow them in perfection obtain them from Mr. Cuthill, and strictly adhere to the mode he prescribes for cultivating them, and they will be well rewarded for their trouble.—*W. D.*

Ice-houses.—My ice-house is nearly full at this time, being a large one. It lost but little in the late singular season. It is the one devised and arranged by "A. E. W.," and described by him in the *Chronicle*, p. 117, 1844. I attribute the success of it to the efficient drainage by faggots.—*Micklewell.*

Rose Catalogues.—Taking some interest in whatever relates to Roses, I was glad to see a hint bestowed in the *Chronicle* upon the Rose-growers, as to the mode of setting forth their catalogues. Inaccuracy of names seems unavoidable, and no doubt Mr. Wood is often quite as much at a loss as this customer. But the purchaser certainly has cause of complaint when he compares catalogues, and finds the same Rose described as large and small, or light and dark. In Mr. Paul's directions for growing Roses in pots, Nighetos, a tea Rose, is represented as snowy white in one page, and as lemon in another. Madame Despres (China) he calls pale lemon, but Mr. Rivers, pure white. Again, the latter, in his catalogue of last autumn, recommends a selection of the very finest Roses from each class, but I observe in his selection of 20 Noisettes, Lamarque is omitted. Of course such an omission may be an oversight, but it is a strange one; but at all events it must lessen the confidence of the purchaser. I would also add that, in the present day, when good Roses are so numerous, and still on the increase, I deem it quite inexcusable to sell a bad one. I think, too, it would be neither a bad rule nor a harsh one, that when a customer finds he has got a worthless variety, he should be at liberty to demand two good ones for it, as the *amende honorable.*—*Philalethes.* [We hope Rose-growers will take this hint.]

Falkoff Raspberry.—I procured some plants of this Raspberry from Messrs. Youell in March last, and though planted so late, after nearly a fortnight spent in the package, and after the unparalleled drought which succeeded, during which time they were never watered, they more than answer all Messrs. Youell say of them. The fruit was very superior to any I have seen, in size and beauty, and quite equal in flavour to the Antwerp. At the present moment the fine dark large leaf of the plants gives abundant promise for next year, when they will have a much better chance, I hope. I write this as a common act of justice to Messrs. Youell, having observed several attacks on their Raspberry.—*W. D. F.* [Not in our columns; for we know the variety to be excellent.]

Societies.

HORTICULTURAL SOCIETY.

Oct. 1.—R. W. Barchard, Esq., in the chair. From Mr. Robertson, gr. to Mrs. Lawrence, was a collection of plants containing a most beautiful specimen of Aphelandra cristata, nearly six feet high, producing six large heads of brilliant scarlet flowers. This plant, when grown to the same state of perfection as this specimen, has no equal in the stove at this season, its richly coloured showy blossoms presenting a most imposing appearance. In the same group were also Erica Solandri. Sedum Sieboldii, a useful, hardy, succulent herbaceous plant from Japan, and the new Franciscea hydrangeifolia, a Brazilian species of little beauty, and possessing no fragrance, for which the other species are remarkable; likewise good plants of Oncidium Harrisonianum, and microchilum; a fine specimen of Epidendrum ciliare, Rodriguesia recurva, producing numerous pendent racemes of yellow blossoms; together with a variety of Maxillaria picta, Peristeria Barkeri, and Clerodendrum splendens, the fine species from Sierra Leone with bright-red flowers. A Knightian Medal was awarded for this, the Aphelandra cristata, and others.—Mr. Jack, gr. to R. G. Loraine, Esq., received a Knightian Medal for a new species of Echites named Carassa, having on it one fully expanded bloom of a beautiful pink colour. The flowers are smaller than those of E. splendens, but are of a better colour, and the plant has a neater foliage than that of the last-named species.—From Mr. Stanley, gr. to H. Baring, Esq., was a good specimen of Rodriguesia planifolia, producing racemes of yellow flowers, having much the appearance of those of R. recurva. A Certificate was awarded for it.—F. R. Symons, Esq., sent cut flowers of seedling Verbenas, named Negro Boy, Prince Alfred, and Prince of Orange.—From Messrs. Veitch and Son, of Exeter, were seven plants of Brachycome, raised from Swan River seeds. They were of various shades of colour, from white to deep blue. From the same collection were also flowering bulbs of Pentlandia miniata, and Stenomesson aurantiacum.—Mr. Plant, gr. to J. H. Schroder, Esq., sent a variety of Gesnera zebrina, and a good plant of Zygopetalum crinitum.—From Mr. Fowle, of Brixton, was a seedling Fuchsia named Vuurberg.—Mr. Jackson, of Kingston, contributed Chironia floribunda, a pretty species with bright pink flowers, Corethostylis bracteata, a handsome species of Begonia from the Organ mountains, resembling B. sanguinea but different, having the red-coloured stems and leaf-stalks covered with small transparent scales; a Lycium with small tube-shaped violet blossoms; and a plant of Griffinia hyacinthina, producing a fine truss of ultra-marine blue flowers. A Certificate was awarded for the Begonia, and Chironia floribunda.—Of Fruit there was a considerable quantity.—From Mr. Henderson, gr. to Sir G. Beaumont, Bart., was an Enville Pine-apple, weighing 5 lbs. 2 oz., and measuring 17 inches in circumference and 11 inches in length; the number of pips was 15. It was said to have been grown on Mr. Hamilton's system; the sucker was not allowed to come away until last year's fruit, which only weighed 3 lbs., was ripe.—A Banksian Medal was awarded to Mr. Povey, gr. to the Rev. J. Thornycroft, for two handsome specimens of Black Jamaica Pine-apples (miscalled Montserrats), the largest of which weighed 5 lbs., and measured 17 inches in circumference and 9 inches in length; the number of pips was 9.—A Certificate was also awarded to Mr. Gold, gr. to Sir W. W. Dixie, Bart., for two Queen Pines weighing 4 lbs. 8 oz., and 4 lbs. 10 oz., and measuring 15 inches in circumference and 10 inches in length; the number of pips was 9; they were fair specimens of good cultivation.—For Grapes a Knightian Medal was awarded to Mr. Davy, gr. to G. Smith, Esq., for very fine bunches of Black Hamburgh, and of what is called Wilmot's New Black Hamburgh, but which is apparently a different sort. The berries of this variety are much more fleshy than those of the other, and they are also much larger, and are remarkable for having the surface covered with small indentations, as if they had been beaten by a hammer; the bunches were beautifully covered with bloom.—R. Thompson, Esq., sent three good clusters of Muscat of Alexandria Grape, the heaviest of which weighed 2 lbs. 7 oz.—From Mr. Standen, gr. to Mrs. Keats, was a box containing black bunches of Black Hamburgh Grapes, grown on the open wall; and Mr. Beck, of Isleworth, also produced from the open wall good samples of the same; the latter were cut from Vines managed according to Mr. Hoare's plan.—From Mr. Fish, gr. to H. H. Oddie, Esq., were specimens of his hardy green-fleshed Melon, weighing 3 lbs. each; they were stated to have been the produce of a fourth crop from the same plants. The linings of the bed (which is described at p. 296, 1844), have never been renewed, the only alteration since its first formation being the addition of any vegetable rubbish from the kitchen garden that would give out heat in decaying. Along with these Mr. Fish sent a Cassauba, green-fleshed variety, weighing 2 lbs. 3 oz.; and samples of French Crab, of last year's growth, in good preservation.—J. M. Wranch, Esq., sent fruit of the double-blossomed Peach.—From Mr. J. B. Lawrence, was a glass globe containing growing plants; it was similar to those globes in which gold-fishes are kept, with a piece of glass laid over the top of it; thus keeping the plants as if in a Ward's case.—From the garden of the Society were specimens of Sedum Sieboldii, Bouvardia splendens, having fine heads of vermilion blossoms melting off into a fine rose-colour, Erica transparens, Babingtonia camphorosmæ, a handsome New Holland plant, Begonia acuminata, the yellow variety of Gloriosa superba, and Oncidium Suttoni, together with cut flowers of Lupinus semperflorens, L. arvensis, and a branch of Cornus mascula covered with fruit, which is of no value to eat, being very austere, but pretty on account of its fine red colour. This hardy shrub is not uncommon in gardens, but seldom fruits now-a-days in this country. Of fruit from the garden there were among Pears Louise Bonne (of Jersey), an excellent variety; Belle et Bonne, a large and handsome sort, and in some seasons very good; Aston Town, a good standard Pear, although small, and well adapted for exposed situations, as it is not apt to be blown down; Thompson's, an excellent sugary variety which, owing to the dry season, has ripened much earlier than usual; Buffams, singular on account of its colour; and the Flemish Beauty, an excellent variety, which requires to be gathered before the fruit parts readily from the tree, otherwise, instead of being sugary and melting, it is dry and perfumed. Among Apples there were Mère de Menage, a good kitchen sort; Brabant Bellefleur; Hollandbury; Pomme Violette, singular on account of its dark violet colour, with bloom like a Plum; and Bedfordshire Foundling: the latter is a strong-growing tree, which does not usually bear until it attains a large size, but by taking it up and replanting, by root-pruning, or by pinching off the ends of the shoots after midsummer, it is found to produce fruit in abundance at an early age.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

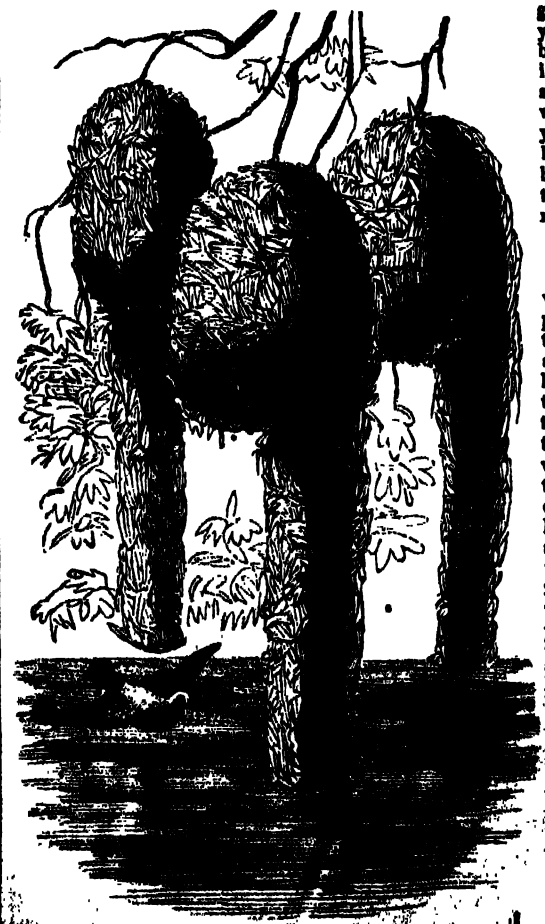
Sept. 20.—This fine display of fruits and flowers took place at the Society's Garden, Inverleith. The subjects for prizes were on this occasion very numerous.—For Peaches, among five competitors, the Silver Medal was awarded to Mr. J. S. Thomson, gr. to Viscount Strathallan, for Red Magdalen, or Royal George, Montauban, and Galande; 2, Mr. P. Crocket, gr. to Col. Ferguson, for Royal Charlotte, Bellegarde or Galande, and Twyford.—For Nectarines, among six competitors, the Medal was assigned to Mr. W. Sharpe, gr. to Sir J. S. Richardson, Bart., for the Vermash and Elruge.—For three sorts of Grapes, the Medal was awarded to Mr. J. Gow, gr. to Count de Flahault, for Black Prince, Chasselas Musqué, and Black Gibraltar.—For Muscats of Alexandria there were five competitors. The Medal was awarded to Mr. T. Clement, gr. to C. Kinnear, Esq.; and a second premium to Mr. Crocket.—In Black Hamburghs there were seven competitors. The Silver Medal was assigned to Mr. M. Carmichael, gr. to W. Murray, Esq., of Polmaise; the clusters weighing about 5 lbs. each, and having been produced in a Vinery heated by the circulation of warm air from a stove or hot air-chamber, the air being kept dry or rendered moist by being made to pass through a dry or a wet curtain (see p. 500, 1844). A second premium was voted to Mr. Crocket.—In Frontignans there were five competitors. The first prize was voted to Mr. J. Addison, gr. to the Earl of Wemyss, for the White and the Black Frontignan. The second premium was again awarded to Mr. Crocket.—The Pine-apples produced were excellent. For an Enville, weighing 4 lbs., the Silver Medal was voted to Mr. Gow, Tullyallan. For a large Queen, the Silver Medal was voted to Mr. R. Gardiner, gr. to the Earl of Stair; and a second premium to Mr. Gow.—The show of Apricots was uncommonly good. The Silver Medal was assigned to Mr. Crocket, for Royal, Moorpark, and Hemskirke; and a second premium to Mr. J. Thomson, gr. to W. Keith, Esq., for Moorpark, Brussels, and Roman.—For the best Plums, exclusive of Green Gage, the premium was found due to Mr. R. Vair, gr. to J. Williamson, Esq., for Coe's Golden Drop, La Royale, and Nectarine Plum; and for fine Green Gages, premiums were voted to Mr. Thomson and Mr. Gardiner.—The competition in Melons was extensive, and two premiums were given; the first to Mr. W. Kerr, gr. to R. Brown, Esq., the kind being the Duke of Bedford, a green-fleshed sort of high flavour; and the next to Mr. C. Macintosh, gr. to J. Tod, Esq., also for the Duke of Bedford Melon.—In Pears the competition was rather limited, yet two premiums were awarded; the first for Jargonelles of very large size, to Mr. G. Taylor, gr. to G. Broad, Esq.; and the next to Mr. Addison.—The show of Cucumbers was very fine. For the best brace, of the Long Smooth Green kind, the Bronze Medal was voted to Mr. W. Martin; and a premium was awarded to Mr. H. Aitken, gr. to P. G. Skene, Esq., for a sort called the Irish Free-bearing.—For Dahlias, the small piece of Plate offered by the Society for the 20 finest Dahlia blooms produced by Nurserymen, was assigned to Messrs. J. Dickson and Sons, the kinds being

Standard of Perfection, Prince of Waterloo, Hero of Stonehenge, Prince Albert, Sure Enough, Beauty of the Plain, Mrs. Shelley, Lee's Bloomsbury, Antagonist, President of the West, Rising Triumph, Lady St. Maur, Admiral Stopford, Beauty of Bucks, Burnham Hero, Perpetual Grand, Nonpareil, Sir Robert Sale, Phenomenon, and Beauty of Sussex. Two other nursery collections were found to be of great merit, and nearly equal to each other; and the Committee therefore voted the Society's Silver Medal for each—to Messrs. Carstairs, Kelly, and Co., and to Messrs. T. and W. Handasyde.—For the Prize of three sovereigns offered by the Society for the finest 18 blooms produced by Practical Gardeners, there were no fewer than 11 competitors. The successful candidate was Mr. W. Thom, gr. to Capt. M. Innes, whose flowers were, Standard of Perfection, Mrs. Shelley, Sphere, Prince of Wales, Essex Triumph, Westbury Rival, Antagonist, Hero of Stonehenge, Lady Borland, Lady St. Maur, Blue Bonnet, Burnham Hero, Coronation, Victor, Prince Albert, Sir Robert Sale, Attila, and Sir John Stewart Richardson. Two other collections sent were each rewarded with the Society's Silver Medal. They were from Mr. Thomson, gr. to W. Vere, Esq., and from Mr. Addison.—The Medal offered for the best 12 blooms produced by Amateurs who cultivate their own plants, was gained by Mr. A. Ambrose, with Phenomenon, Mrs. Shelley, Prince of Wales, Essex Triumph, Sir J. S. Richardson, Duchess of Richmond, Indispensable, Bridesmaid, Bedford Surprise, Antagonist, Maria, and Lady St. Maur; and a premium was voted to Mr. J. Sanderson.—A number of Seedling Dahlias, the produce of 1843 or of the present year, were exhibited; but none of them excelled the finer varieties now in cultivation. No premium was awarded.—Two Collections of Carnations, flakes and bizarres, were much admired. The Silver Medal was awarded to Mr. D. Foulis, gr. to J. Tytler, Esq., the flowers being Simpson's Marquis of Granby, Wood's Commander-in-Chief, Lady Ely, Rainsforth's Game Boy, Elliot's Duke of Sutherland, Ely's Duke of Bedford, Mr. Grainger, Ely's Magnificent, Adinbroke's Lydia, Dalton's Lancashire Lass, Tutchet's Don Juan, and Duchess of Devonshire; and the bronze Medal to Mr. Thomson, for the other collection. A premium for Picotees was likewise awarded to Mr. Foulis.—The display of Hollyhocks was rich, and two awards were made—the first to Mr. Foulis, and the next to Mr. Alexander Foulis, gr. to Admiral Sir Philip Durham.—At this meeting an unusual number of articles were brought forward, for which no premiums had been announced in the programme; and several being very meritorious, received marks of distinction. A stand consisting of above 80 seedling Pansies, some of them of great beauty, was considered deserving of the Silver Medal, which was accordingly voted to the raiser, Mr. J. Finlayson, of Kincardine. — Another medal was awarded to Mrs. Erskine, for a collection of nine distinct kinds of Oranges.—An extra premium was voted to Mr. J. Macnaughton, gr. to J. Wauchope, Esq., for collections of several kind of fine fruits.—From Leith Walk Nurseries were exhibited plants of the golden-ribbed Beet (Poirée à cardes jaunes of the French), of a very elegant appearance; and also specimens of the Chou Nantais, a neat crisp little Cabbage, and Maclellan's new winter Cabbage, apparently a very good variety.—Messrs. Handasyde sent a collection of 80 named Dahlias, along with 17 new fancy striped kinds, of a very striking appearance, although not admissible to the florist's stand.—Messrs. Carstairs, Kelly, and Co., contributed a collection of named Hollyhocks, with guard-petals, some of them of great beauty.—Mr. Oliver sent stands of French and African Marigolds, the latter of uncommon size, and 30 very beautiful varieties of China Aster.—Mr. Anderson produced curious seedling Fuchsias, one being a cross between F. Chandlerii and F. decortiçata, the first time these have been hybridised.—From Professor Dunbar were beautiful Cape Heaths, particularly E. inflata, reflexa, alba, verticillata, Irbyana, and retorta.—Dr. Neill sent Acropera Loddigesii, with 30 flowering spikes, and Grobya Amherstiæ, with five spikes of flowers.—Messrs. J. Dickson and Sons showed two magnificent flowering specimens of Gesnera zebrina, one of them 8 feet in circumference around the branches.—Other contributors were, Mr. Deans, who sent a Seedling Apple of considerable promise, and also Seedling Dahlias; and Mr. Kinnear, who showed remarkably fine clusters of the White Raisin and Southfield Black Grapes, produced on the back wall of his vinery; Mr. Dunchar contributed very late Gooseberries, and excellent specimens of the Borsdorff Apple; and Mr. Goodall sent Astrachan Apples and Retarded Cherries; Mrs. Brown, large Pears; Mr. Bridges, large Swedish Turnips; and Mr. Anderson, very large White Turnips.

Reviews.

Bird-Architecture. By James Rennie. Vol. XI. of Knight's Weekly Volume.

It is so seldom that the subjects of Mr. Knight's admirable weekly work relate to matters of which we can take notice, that we gladly avail ourselves of the opportunity of mentioning them, which is afforded by the republication of the present volume. If there is one part of the creation more calculated than another to excite admiration, it is the wonderful skill with which birds and insects construct their habitations. The wisdom of the contrivances, their perfect adaptation to the wants and means of the little artificers, and the dexterity with which the wonderful power of instinct teaches these creatures to construct them, are among the most striking evidences of the power and wisdom of the Creator.



"Birds of the same kind," says Ray, "make their nests of the same materials, laid in the same order, and exactly of the same figure, so that by the sight of the nest one may certainly know what bird it belongs to. And this they do though living in distant countries, and though they never saw, nor could see any nest made, that is, though taken out of the nest and brought up by the hand; neither were any of the same kind ever observed to make a different nest either for matter or fashion. This, together with the curious and artificial contexture of such nests, and their fitness and convenience for the reception, hatching, and cherishing the eggs and young of their respective builders (which we have before taken notice of), is a great argument of a superior Author of their and other natures, who hath endued them with these instincts, whereby they are, as it were, acted and driven to bring about ends which themselves aim not at (so far as we can discern) but are directed to; for (as Aristotle observes) οὔτε τέχνῃ, οὔτε ζητήσαντα, οὔτε βουλευσάμενα ποιεῖ ('They act not by art, neither do they inquire, neither do they deliberate about what they do.') And therefore, as Dr. Cudworth saith well, 'They are not masters of that wisdom according to which they act, but only passive to the instincts and impresses thereof upon them.' And, indeed, to affirm that brute animals do all these things by a knowledge of their own, and which themselves are masters of, and that without deliberation and consultation, were to make them to be endued with a most perfect intellect, far transcending that of human reason; whereas it is plain enough that brutes are not above consultation, but below it; and that these instincts of nature in them, are nothing but a kind of fate upon them."

The purpose of Mr. Rennie's book is to explain the details of these things, by the assistance of previous ornithological writers. The work is perhaps the most successful of the publications of its author; it gives in a popular way a great deal of entertaining information, and Mr. Knight has acted judiciously in reproducing it. It seems exactly the kind of publication which will be acceptable to the million, who, we hope, are purchasers of these weekly volumes.

An anecdote concerning the habits of the pensile grosbeak will, we trust, excite those who are interested about birds to make the acquaintance of the rest of the work.

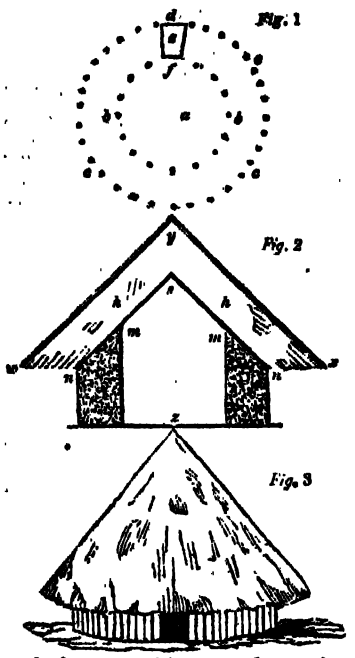
"Another of these gregarious African birds is the pensile grosbeak, which is about the size of a house-sparrow, and makes a basket-nest of straw and reeds, interwoven into the shape of a bag, with the entrance below, while it is fastened above to the twig of some tree, chiefly such as grow on the borders of streams. On one side of this, within, is the true nest. The bird does not build a distinct nest every year, but fastens a new one to the lower end of the old, and as many as five may thus be seen, one hanging from another. From five to six hundred such nests have been observed crowded upon one tree.

"A living author of reputation thus describes these nests; but we must premise that we do not coincide with

his opinion of the structure being designed for defence: 'Several varieties of the finch tribe, in South Africa, suspend their nests from the branches of trees, especially where they happen to impend over a river or precipice. The object of this precaution is obviously to secure their offspring from the assaults of their numerous enemies, particularly the serpent race. To increase the difficulty of access to these 'tree-rocked cradles,' the entrance is always from below, and frequently through a cylindrical passage of twelve or fifteen inches in length, projecting from the spherical nest, exactly like the tube of a chemist's retort. The whole fabric is most ingeniously and elegantly woven of a species of very tough grass; and the wonderful instinct of foresight (or whatever else we may choose to call it) displayed by the little architect in its construction, is calculated to excite the highest admiration. I have often seen twenty or more of these beautiful nests hanging from a single tree.'"*

Garden Memoranda.

Erratum.—In the report of the Horticultural Society's Garden, last week, p. 655, col. *a*, line 28 from top, instead of "Centrosema splendens," read "Camptosema splendens."



Bury Hill, near Dorking.—Your correspondent, "Q.," in his notice of this place, has omitted one of its principal features, namely, the fine plants of Arbutus and Rhododendron that crest the wooded hill behind the house, and which constitute one of its chief beauties. Along the crown of this hill a broad walk is bordered by large plants of most of the best varieties of Rhododendron, and behind, and among these, the new Pines alluded to by your correspondent are dotted about. A collection of hardy Heaths has also been planted in an inclosed spot in front of a covered seat. Besides these inducements to climb the hill, several beautiful views are obtained from its summit. From one point you look down upon the fine sheet of water below the house, and beyond that upon a tract of cultivated country which gradually rises into hills of nearly an amphitheatrical form, thus closing in a very pleasing prospect. By taking down some trees at one end of this elevated walk, a highly picturesque view of the town of Dorking and of Box-hill is opened, the trees which are retained forming, as it were, a frame to the picture. On a knoll in the park, in a line with the walk, a very neat rustic temple has been constructed, and from this spot the prospects are diversified and extensive. The kitchen-garden is a considerable distance from the mansion. Its hothouses once contained perhaps the largest collection of plants of any private garden in Britain, but these were distributed at the death of the former proprietor, and their places are now filled by kinds more in character with the present ornamental style of gardening. In one house there are about 80 varieties of the Camellia, comprising most of the leading sorts, and all in excellent health; and in another house there are some fine plants of the different varieties of Azalea indica. Mr. Scott has raised several beautiful seedlings from lateritia, most of them having flowers in the style of Gledstanesii, but superior, while some are pure white. He also has some of the ledifolia breed, which are a great improvement upon the original white. The Rhododendron is worked here almost with as great facility as the Apple. Seedlings from the common kinds, growing in nursery rows, are budded standard high with improved varieties, and soon form handsome heads. Smaller plants in pots are grafted near the ground at almost all seasons of the year; in the summer months they merely require to be kept close and moist by means of a hand-glass, but in spring and autumn a little artificial heat is necessary. By using these means the splendid hybrids which have been bred from arboreum may in a few years be made as plentiful as ponticum. It may not be generally known that the Chinese Azalea will take by inarching upon the Rhododendron; but whether this union will produce any practical advantage remains to be proved.—*W.*

Miscellaneous.

Ice-houses.—In England these receptacles of frozen water are, generally, under ground, and always, if possible, under the shade of trees, the opinion being, that the main thing, if not the only thing, is to keep away the heat. The heat is to be kept away certainly; but moisture is the great enemy of ice; and how is this to be kept away, either under ground, or under the shade of trees? Abundant experience has proved, that no thickness of wall, that no cement of any kind, will effectually resist moisture. Drops will, at all times, be seen hanging on the under side of an arch of any thickness, and made of any materials, if it have earth over it, and even when it has the floor of a house over it; and wherever the moisture enters the ice will quickly melt. Ice-houses should therefore be, in all their parts, as dry as possible; and they should be so constructed, and the ice so deposited in them, as to insure the running away of the meltings as quickly as possible, whenever such meltings come. Anything in the way of drains or gutters, is too slow in its effect; and therefore there must be something that will not suffer the water, proceeding from any melting, to remain an instant. In the first place, then, the ice-house should stand in a place quite open to the sun and air; for whoever has travelled even but a few miles (having eyes in his head) need not be told how long that part of a road from which the sun and wind are excluded by trees, or hedges, or by anything else, will remain wet, or at least damp, after the rest of the road is even in a state to send up dust. The next thing is to protect the ice against wet, or damp, from beneath. It should, therefore, stand on some spot from which water would run in every direction; and if the natural ground present no such spot, it is no very great job to make it. Then come the materials of which the house is to consist. These, for the reasons before mentioned, must not be bricks, stones, mortar, or earth; for these

* Pringle's Ephemerides, Notes.

are all affected by the atmosphere; they will become damp at certain times, and dampness is the great destroyer of ice. The materials are wood and straw. Wood will not do; for though not liable to become damp, it imbibes heat fast enough; and, besides, it cannot be so put together as to shut out air sufficiently. Straw is wholly free from the quality of becoming damp, except from water actually put upon it; and it can, at the same time, be placed on a roof, and on sides, to such a degree of thickness as to exclude the air in a manner the most perfect. The ice-house ought, therefore, to be made of posts, plates, rafters, laths, and straw. The best form is the circular; and the house, when made, appears as I have endeavoured to describe it in *Fig* 3 of the plate. *Fig* 1, *a*, is the centre of a circle, the diameter of which is ten feet, and at this centre you put up a post to stand fifteen feet above the level of the ground, which post ought to be about nine inches through at the bottom, and not a great deal smaller at the top. Great care must be taken that this post be perfectly perpendicular; for, if it be not, the whole building will be awry. *b b b* are fifteen posts, nine feet high, and six inches through at the bottom, without much tapering towards the top. These posts stand about two feet apart, reckoning from centre of post to centre of post, which leaves between each two a space of 18 inches. *c c c c* are fifty-four posts, five feet high, and five inches through at the bottom, without much tapering towards the top. These posts stand about two feet apart, from centre of post to centre of post, which leaves between each two a space of nineteen inches. The space between these two rows of posts is four feet in width, and, as will be presently seen, is to contain a wall of straw. *e* is a passage through this wall; *d* is the outside door of the passage; *f* is the inside door; and the inner circle, of which *a* is the centre, is the place in which the ice is to be deposited. Well, then, we have now got the posts up; and, before we talk of the roof of the house, or of the bed for the ice, it will be best to speak about the making of the wall. It is to be made of straw, Wheat-straw, or Rye-straw, with no rubbish in it, and made very smooth by the hand as it is put in. You lay it in very closely and very smoothly, so that if the wall were cut across, as at *g g*, in *Fig*. 2 (which *Fig*. 2 represents the whole building cut down through the middle, omitting the centre post), the ends of the straw would present a compact face as they do after a cut of a chaff-cutter. But there requires something to keep the straw from bulging out between the posts. Little stakes as big as your wrist will answer this purpose. Drive them into the ground, and fasten, at top, to the plates, of which I am now to speak. The plates are pieces of wood which go all round both the circles, and are nailed on upon the tops of the posts. Their main business is to receive and sustain the lower ends of the rafters, as at *m m* and *n n*, in *Fig*. 2. But to the plates also the stakes just mentioned must be fastened at top. Thus, then, there will be this space of four feet wide, having on each side of it a row of posts and stakes, not more than about six inches from each other, to hold up, and to keep in its place, this wall of straw. Next come the rafters, as from *s* to *n*, *Fig*. 2. Carpenters best know what is the number and what the size of the rafters; but from *s* to *m* there need be only about half as many as from *m* to *n*. However, carpenters know all about this. It is their every-day work. The roof is forty-five degrees pitch, as the carpenters call it. If it were even sharper, it would be none the worse. There will be about thirty ends of rafters to lodge on the plate, as at *m*; and these cannot all be fastened to the top of the centre post rising up from *s*; but carpenters know how to manage this matter, so as to make all strong and safe. The plate which goes along on the tops of the row of posts, *b b b*, must, of course, be put on in a somewhat sloping form; otherwise there would be a sort of hip formed by the rafters. However, the thatch is to be so deep, that this may not be of much consequence. Before the thatching begins, there are laths to put up on the rafters. Thatchers know all about this, and all that you have to do is, to take care that the thatcher tie the straw on well. The best way, in a case of such deep thatch, is to have a strong man to tie for the thatcher. The roof is now raftered, and it is to receive a thatch of clean, sound, and well-prepared Wheat or Rye-straw, four feet thick, as at *h h* in *Fig*. 2. The house having now got walls and roof, the next thing is to make the bed to receive the ice. This bed is the area of the circle of which *a* is the centre. You begin by laying on the ground round logs, eight inches through, or thereabouts, and placing them across the area, leaving spaces between them of about a foot. Then, crossways on them, poles about four inches through, placed at six inches apart. Then, crossways on them, other poles about two inches through, placed at three inches apart. Then, crossways on them, rods as thick as your finger, placed at an inch apart. Then upon these, small, clean, dry, last winter-cut twigs, to the thickness of about two inches; or, instead of these twigs, good, clean, strong Heath, free from Grass and Moss, and from rubbish of all sorts. This is the bed for the ice to lie on; and, as you see, the top of the bed will be seventeen inches from the ground. The pressure of the ice may, perhaps, bring it to fourteen, or to thirteen. Upon this bed the ice is put, broken and pummelled, and beaten down together in the usual manner. Having got the bed filled with ice, we have next to shut it safely up. As we have seen, there is a passage (*e*). Two feet wide is enough for this passage, and, being as long as the wall is thick, it is, of course, four feet long. The use of the passage is this: that you may have two doors, so that you may, in hot or damp weather, shut the outer door, while you have the inner door open. This inner door may be of hurdle-work and straw, and covered, on one of the sides, with sheep-skins with the wool on, so as to keep out the external air. The outer door, which must lock, must be of wood made to shut very closely, and, besides, covered with skins like the other. At times of great danger from heat, or from wet, the whole of the passage may be filled with straw. The door (*p*, *Fig*. 3) should face the north, or between north and east. As to the size of the ice-house, that must, of course, depend upon the quantity of ice that you may choose to have. A house on the above scale, is from *w* to *x* (*Fig*. 2) twenty-nine feet; from *y* to *z* (*Fig*. 2) nineteen feet. The area of the circle, of which *a* is the centre, is ten feet in diameter, and as this area contains seventy-five superficial feet, you will, if you put ice on the bed to the height of only five feet (and you may put it on to the height of seven feet from the top of the bed), you will have three hundred and seventy-five cubic feet of ice, and, observe, a cubic foot of ice will, when broken up, fill much more than a Winchester bushel: even Dives himself would hardly call for more than two bushels of ice in a day; for more than two bushels a day it would be, unless it were used in cold as well as in hot weather. As to the expense of such a house, it could, in the country, not be much. None of the posts, except the main or centre-post, need be very straight. The other posts might be easily culled from tree-lops, destined for fire-wood. The straw would make all straight. The plates must of necessity be short pieces of wood; and, as to the stakes, the laths, and the logs, poles, rods, twigs, and Heath, they would not all cost twenty shillings. The straw is the principal article; and, in most places, even that would not cost more than two or three pounds. If it last many years, the price could not be an object; and if but a little while, it would still be nearly as good for litter as it was before it was applied to this purpose. How often the bottom of the straw walls might want renewing I cannot say, but I know that the roof would, with few and small repairs, last well for ten years. I have said that the interior row of posts is to be nine feet high, and the exterior row five feet high. I, in each case, mean, with the plate inclusive. I have only to add, that by way of superabundant precaution against bottom wet, it will be well to make a sort of gutter, to receive the drip from the roof, and to carry it away as soon as it falls. Now, after expressing a hope that I shall have made myself clearly understood by every reader, it is necessary that I remind him, that I do not pretend to pledge myself for the complete success, nor for any success at all, of this mode of making ice-houses. But, at the same time, I express my firm belief, that complete success would attend it; because it not only corresponds with what I have seen of such matters, but I had the details from a gentleman who had ample experience to guide him, and who was a man on whose word and judgment I placed a perfect reliance. He advised me to erect an ice-house; but not caring enough about fresh meat and fish in summer, or, at least, not setting them enough above "prime pork" to induce me to take any trouble to secure the former, I never built an ice-house. Thus, then, I only communicate that in which I believe; there is, however, in all cases, this comfort, that if the thing fail as an ice-house, it will serve all generations to come as a model for a pig-bed.—*Cobbett's Cottage Economy*—[16*th Ed*.]

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Now that fires will be kept up regularly for this house, it may be as well to remark that a higher night temperature than was recommended in the spring is now necessary, in order to ripen off late growths as soon as possible; 65° should therefore be the minimum for fire heat during this month, even although the weather should be dull at times. In spring the temperature in plant-houses is regulated, in a great measure by the quantity of sunlight we receive—the more sun the harder you may force, and the contrary—but now there is no occasion to be so particular. However, if the ripening process can be finished thoroughly before the end of October, without much strain on the fires, so much the better. When plants are well ripened in time, much less fire will be needed to keep them in proper condition through the winter, and experience has clearly proved that the more thoroughly plants are kept at rest in winter, the better they flower in the following season. This applies to plants in general.

Conservatory.—The standard temperature for our conservatory here in winter is 45°; it never exceeds that by fire-heat, and for six weeks after Christmas it is kept at about 40°, and little or no air is admitted artificially for four months. With this treatment most of the half-stove climbers flourish and bloom as well as could be wished—Stephanotus floribundus, Ephites suberacta, Ipomœa Horsfallia, Combretum purpureum, and many others are thus treated. About this time we remove the soil from round their stems, down to the main roots, and replace it with charcoal, broken small; this guards them against damp. The surfaces of the borders is kept porous by frequent stirring, and no water is given till the leaves begin to droop for want of it, and then as much is given at once as will reach the bottom of the border; in a day or two afterwards a little dry soil is placed over the parts watered, to lessen evaporation. On this principle all plants in a dormant state in winter should be watered whether they are in borders or pots, providing these are well drained. Speaking of conservatory climbers, I must mention an old plant, the Ipomœa bona-nox, which proved a great novelty here this autumn. This plant—the "midnight lily" of travellers—flowers only at night, hence, like the Cereus grandiflorus, great interest is attached to it by the curious. The company here stream out into the conservatory to see the lily-white Ipomœa, or the flowers are gathered and sent in to be admired. Next week I shall say how it may be treated in other places.

Pits, Greenhouse, &c.—If there is anything in gardening which requires reformation more than another, it is the distribution of plants in their winter quarters. The only rule attended to at present, in nine cases out of ten, is to place the tallest plants at the back of the greenhouse stage or pit, then the next in size, and so on, till the lowest fill up the front row. In this way plants the most dissimilar in their nature, and requiring widely different treatment, as Heaths, Pelargoniums, Camellias, Calceolarias, &c. are indiscriminately mixed together, so that one can hardly conceive how, under the best management, one-half of the plants can be kept from destruction through the winter. Nurserymen could never "make both ends meet" if they managed their stock in this way; with them you hear, as bye-words, New Holland-house, Camellia-pit, Heath-house, Pelargonium-house, and I know not how many more houses and pits all devoted to distinct families of plants. In large private establishments also, compartments are allotted to the larger groups of plants, and the miscellaneous stock is divided among the large Families, as the nature of each plant will suggest. Now, the shortest and the best advice that can be given to the amateur of small means, is to place every plant he possesses of the same genus together, keeping the tallest in each group at the back, as at present, then to follow with the next family whose treatment comes nearest to the first, and so on to the end of the stage or pit.—*D. B.*

II.—FLOWER GARDEN AND SHRUBBERIES.

Out-door Department.

So extensive and varied is the collection of Verbenas which now adorn with their brilliant colours our lawns and flower-gardens, that it is a difficult task even to select those most worthy of cultivation. In colour we have little to wish for except yellows and bright blue, and these we are in a fair way to produce, as I have a sulphur-coloured variety in my possession, and one approaching sulphur has been raised by Mr. Girling, of Stowmarket, either of which, if crossed with the orange-scarlet varieties next season, will probably produce a yellow; and blues must emanate from such varieties as Amethystina, Emma, and others of that character. There is, however, plenty of room for improvement in the form of the flowers, and these, before they are perfect, must be round, flat, and perfectly smooth on the edge, with the petals overlapping, so as to show no indenture, the florets blooming well up to the centre of the truss, and the latter forming, when fully open, half a hemisphere. Of the scarlet varieties, atrosanguinea still continues the best for form and size; Boule de Feu is brighter in colour, as likewise are Ignea and Mollindres superba; formosa elegans and Kyle's speciosa are two orange-scarlet varieties, and very brilliant, but the latter is very liable to mildew early in the season, and consequently soon becomes shabby. Speciosa is synonymous with Incisa coccinea and Zeuxis. Among whites the Queen must be discarded for Princess Royal and Monarch; and in blue Amethystina, Van Gendti, and Hydeana, are the best; Minstrel Boy is a bluish lilac, but is surpassed by seedlings of this year. Stewartii is still the best of the purple class, and Rubra purpurea, reddish purple; Charlwoodii and longiflora are also good. Emma is a very fine variety, of dull purple colour, changing to blue as the flowers fade; and Iveryana is a rosy purple still worthy of cultivation. Renown has dark-red flowers tinged with purple; and Smith's excelsa makes a good corresponding bed; Defiance and Ruby are two varieties inclining to pale red, or ruby colour. Among those of a blush-colour, more or less tinged with rose, may be mentioned Bridesmaid, Tagliosi, Teucrioides carnea, Fortune-teller, and Wood's Princess Royal. Ingramii, Beauty, and variegata are orange-red varieties; Bishopii is rosy lilac, and Beauty Supreme is a very splendid kind of rosy flesh-colour. The best rose-coloured variety is Teucrioides rosea. Among Mr. Girling's varieties the two greatest novelties are Mulberry and Alba lutescens, the former mulberry-coloured and the latter rich cream-colour. Rose d'Amour is a very splendid rose-coloured variety, and Gladiator puts speciosa and the other orange-scarlet varieties out of cultivation. Alba magna is a very large white, and Blanda is a rosy blush-colour; Messenger is a bright lilac. Lovely Rambler has slightly paler flowers, and the Giant has very large trusses of bluish-lilac flowers; rubescens is a reddish purple. The great advantage of these flowers is their large size, vigorous habit, and improved form.—*W. P. A.*

III.—FLORISTS' FLOWERS.

Tulips.—It has often been mentioned to us as a matter of regret, that in the numerous lists given in various publications of the best six or twelve Tulips, that no specific mention is made whether they are feathered or flamed. In answer to this we may urge the uncertainty of the flower, as many varieties which feather beautifully one season will some finely flamed the next. But to afford some guide to young growers or amateurs commencing the cultivation of these favourite flowers, and as it is time all bulbs were now obtained for planting, we subjoin a list of cheap varieties, and sorts which are tolerably steady to their respective characters:—*Feathered Bizarres*—Royal Sovereign, Surpass Optimus, Magnum Bonum, and Surpass Ca'afalque; *Flamed Bizarres*—Polyphemus, Captain White, and Leonotus Posthumous; *Feathered Bybloemens*—Bienfaite, Lawrence's Friend, and Black Bagot; *Flamed Bybloemens*—David, Queen Charlotte, and Roi de Siam; *Feathered Roses*—Triomphe Royale, Lady Crewe, and Count de Virginnes; *Flamed Roses*—Brulante eclatante, Camuse de Craix, Cerise belle forme, and Ponceau tres blanc. We next week shall give the names of a few scarcer sorts of fine properties. *Carnations.*—Keep the potted layers in a close frame till they strike again, taking great care that the leaves are not wet, as this would infallibly endanger their health by inducing them to become spotted. *Pinks.*—Continue to plant out for blooming, and refer to the few back Numbers of the *Chronicle* for the routine of floricultural work which needs doing. *Dahlias.*—Draw up the soil round the stems in a small hillock, to prevent the crowns of the roots being injured by frosts, which we may soon expect.—*J. F., W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—Those who have not the advantage of tanks for supplying bottom-heat to their Pines, generally defer their winter arrangement as long as the heat in the bed continues sufficient. Whenever it declines to about 80° it is time to set about renewing it, by taking away part of the most decayed, turning the remainder, and adding fresh, to make up for what has been taken away. Everything should be in readiness before the job is commenced, in order that the plants may remain out as short a time as possible. Keep those in fruit by themselves, and if wanted to ripen soon, place them at the warmest end of the pit. In replunging, be careful not to put the pots too deep, or to make the tan too firm about them at first, for fear of injury to the roots from over-heating; it is better to incur a little after-trouble than to run any risk. I am of opinion that the plants thrive better when the tan is loose on the surface than when closely patted down; and the risk of injury to the

roots is lessened by allowing a portion of the heat to escape among the foliage of the plants, to which it is beneficial.

Vineries.—Adopt the usual means to keep the vineries containing fruit dry and cool. Grapes not yet ripe will be the better for being kept a little warmer during the day, giving air at the same time that the house is warmed by the pipes or flues. This will also assist to ripen the wood, which is a point of the first importance. In cutting the fruit from spurs, follow the good old practice of pruning back at the same time to the most promising eye; or the more modern one of removing all the eyes except that intended for future bearing, and one at the base of the spur, as recommended in Mr. Robert's Treatise.

Peach houses.—Where the lights have been wholly removed, the inside borders have probably had sufficient rain; and the lights after being repaired and painted, should be put upon the house, to defend the trees and borders from rough weather. ‖

Melons.—If there is still any promising fruit keep them warm and dry, giving air at all favourable opportunities.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Mushrooms.—In the early part of summer I recommended spawning the beds intended for Ridge Cucumbers, vegetable marrow, &c., under the impression that the mulching of the beds, and the shade of the leaves of the plants, would keep the Mushrooms sufficiently cool. The plan answered pretty well, but there is a disadvantage connected with it, from the liability of breaking the leaves and vines of the plants in getting at the Mushrooms, and also from the Mushrooms being rendered thin from the want of sufficient nourishment, on account of such plants as the Vegetable Marrow rooting so near the surface. I would, therefore, recommend for summer produce the forming of small ridges in any cool situation. Two small beds, put up under the shade of large Chesnut-trees, have supplied me plentifully during the summer. All the attention bestowed upon them was protecting them with wattled hurdles, and a slight covering of hay or straw, kept rather moist in dry warm weather, so as to secure a cool and moist atmosphere for the Mushrooms. This is a much better method than attempting to grow them in houses during summer (unless in some underground department), as too often either the Mushrooms are rendered thin and tough from too much heat, or by admitting draughts or currents of air, that cloud humid atmosphere is destroyed in which the Mushroom so much luxuriates. Every opportunity should now be taken for preparing beds for winter produce, as previously adverted to. In earthing beds, I prefer fresh soil of a stiffish nature, though I have had fine crops from covering with light sandy soil. The chief thing in all cases is to render the soil as firm as possible, and leave the surface quite smooth, which will enable you to brush off all extraneous matter without any difficulty. The advantage of having horse and cow-droppings well prepared for forming beds is, that not only will the beds bear longer, but the surface of them will not be so liable to crack into fissures, as when the beds are composed of any comeatable littery matter, merely sufficient to create enough of heat to insure the working of the spawn. Those who have lately made bricks for future supply will find this a favourable time for spawning them if they are sufficiently dry. After filling the holes made on purpose, with spawn of a good quality, proceed to build them on a slight hot bed of dung in an open manner, so that the heat may percolate freely; cover up the heap with long litter; take care that the heat never much exceeds that of new milk; turn the heap occasionally, removing those bricks thoroughly spawned, and when all are done, take them to a dry place, cover them with a little dry litter, and they will keep good for years. *Carrots.*—No time should now be lost in getting the main crops out of the ground, and drying them partially before storing them past for the season. The best remedy I have found for preventing the Carrots being spoiled and disfigured by worms, is taking them early out of the ground. Routine—see former Calendars.—*R. F.*

VII.—COTTAGERS' GARDENS.
